## ZUSAMMENFASSUNG

Die molekularbiologische Untersuchung der Wechselwirkungen zwischen Pathogenen und ihren Wirtszellen ist ein wertvoller Ansatz zur Erschließung bakterieller Pathogenitätsmechanismen und trägt darüber hinaus dazu bei, unser ständig wachsendes Wissen über fundamentale Prozesse in eukaryotischen Zellen zu erweitern. Das Gram-negative, fakultativ intrazelluläre Bakterium *Salmonella* Typhimurium ist ein gängiger Modellorganismus, um den intrazellulären Lebensstil bakterieller Pathogene und deren Einfluss auf Wirtszellprozesse zu erforschen. In der vorliegenden Arbeit wurde ein Durchflusszytometrie-basierter Hochdurchsatz RNA Interferenz (RNAi) Screen einer humanen Kinase-Bibliothek etabliert und durchgeführt, um die Wirtszellfaktoren zu entschlüsseln, welche in die intrazelluläre Replikation von *Salmonella* Typhimurium involviert sind. Ein Salmonellen-Stamm, der zwei fluoreszierende Reporterproteine exprimiert, wurde konstruiert, um die bakterielle Replikation und die metabolische Aktivität in infizierten Wirtszellen zu detektieren. Dies ermöglichte es, die Auswirkungen fehlender Wirtszellfaktoren auf das intrazelluläre Wachstum von Salmonellen zu untersuchen. In Vorversuchen wurde die humane Epithelzelllinie HeLa als adäquate Zelllinie für die Durchführung der Hochdurchsatzexperimente (Screen) bestimmt sowie geeignete Infektionsbedingungen festgelegt. Als inhibitorische Kontrolle für den Screen diente die Depletierung der GTPase Rab7A, welche einen essentiellen Faktor während der Salmonelleninfektion darstellt. Nachdem die technische Stabilität der Untersuchungsmethode und die Genauigkeit der ermittelten Daten überprüft wurden, konnte die Anwendbarkeit des Systems im Hochdurchsatz anhand ausgewählter chemischer Inhibitoren sowie einer innerhalb der Abteilung zusammengestellten siRNA-Bibliothek gezeigt werden. Der Einsatz der humanen Kinase-Bibliothek lieferte 48 potentielle Kandidatengene, von denen 15 in einer anschließenden Validierung als die Infektion beeinflussende Faktoren identifiziert werden konnten. Die Mitogen-aktivierte Protein Kinase (MAPK) MKK7, deren Herunterregulation eine verminderte bakterielle Replikation zur Folge hatte, wurde für eine weitergehende funktionelle Charakterisierung ausgewählt. Es konnte gezeigt werden, dass reduzierte MKK7 Proteinmengen eine Verringerung des Proteins zytosolische Phospholipase A2 (cPLA2) zur Folge hatten. Dieser Einfluss auf die Menge von cPLA2 beruhte nicht auf einer direkten Interaktion der beiden Proteine, sondern auf der transkriptionellen Regulation von cPLA2 durch MKK7, wie die Herunterregulation der mRNA nach MKK7 Depletion zeigte. Die Bedeutung von cPLA2 für die bakterielle Infektion wurde durch die Salmonellen-induzierte, dauerhafte Phosphorylierung des Faktors deutlich und konnte darüber hinaus durch Replikationsvergleiche in cPLA2-depletierten und nicht-depletierten Zellen bestätigt werden. Weitergehende mikroskopische Experimente deuteten darauf hin, dass die Phospholipase A2 für den fehlerfreien Aufbau von Salmonellen-induzierten Filamenten notwendig ist, welche unerlässlich für die Salmonellenreplikation in Epithelzellen sind.

## ABSTRACT

The study of pathogen-host cell interactions on the molecular level is a valuable tool to reveal bacterial pathogenicity mechanisms and, moreover, contributes to our increasing knowledge of fundamental cellular processes of eukaryotic cells. The Gram negative, facultative intracellular bacterium *Salmonella* Typhimurium is a well established model organism to investigate the intracellular lifestyle of bacterial pathogens and their modulation of host cell processes. In this work, a flow cytometry (FACS) based high-throughput RNA interference (RNAi) human kinome screen was established and performed in order to elucidate host cell factors involved in the intracellular replication of *Salmonella* Typhimurium. An elaborate *Salmonella* strain expressing two fluorescent reporter constructs was generated which allowed for monitoring the bacterial replication and metabolic activity within infected cells. This made it possible to robustly assess the impact of host cell gene knock down on *Salmonella* intracellular growth. The human epithelial cell line HeLa was evaluated as the suitable cell line for the screening experiments and proper infection conditions were determined. The knock down of the host cell small GTPase Rab7A was selected as the inhibitory control for the screen due to the essential role of this factor during the infection process of the pathogen. The technical stability of the FACS assay and the accuracy of the acquired data were verified before successfully testing the applicability of the system with a small screen employing chemical inhibitors and with an in-house RNAi library, serving as a proof-of-principle. The human kinome-wide siRNA library was screened and 48 candidates were chosen for further validation. Among these, 15 host cell genes were identified to influence *Salmonella* intracellular replication. The mitogen activated protein kinase (MAPK) MKK7, whose depletion caused a decrease in bacterial replication, was selected for a more profound functional characterization to reveal its role during *Salmonella* infection. It could be demonstrated that the knock down of MKK7 caused a decrease in phospholipase A2 (cPLA2) protein levels. This control of cPLA2 levels through MKK7 did not occur via a direct interaction but rather by a transcriptional regulation of cPLA2 which was demonstrated by reduced cPLA2 mRNA levels upon knock down of MKK7. A role for cPLA2 during bacterial intracellular lifestyle was implicated by the finding that *Salmonella* induced a permanent phosphorylation of the phospholipase. The necessity of cPLA2 was confirmed with replication assays in cPLA2 depleted cells using siRNA and shRNA mediated knock down strategies. Microscopic experiments indicated that the phospholipase A2 is involved in the accurate generation of *Salmonella*-induced filaments, structures that were reported to be indispensable for replication.

wt	wild type

# I Introduction

## I.1 RNA interference

### I.1.1 A short chronology

RNA interference (RNAi) describes a molecular pathway in which different RNA species are involved in the silencing of target genes either by inducing the cleavage of target mRNA (dsRNA and siRNA) or by inhibiting the translation of the mRNA (microRNA). During the last years a major research focus has been put on regulatory RNAs unravelling an increasing number of complex regulation mechanisms.

The first unintended indication for a mechanism of RNAi, also termed posttranscriptional gene silencing (PTGS), came from a study in plants performed by Napoli et al. (1990). The group introduced a chalcone synthase (*chsA*) transgene, responsible for the purple colour of the leaves, into petunia flowers. Unexpectedly, some of the transgenic plants produced pure white or variegated colours. Moreover, the level of *chsA* mRNA in these plants was decreased which was not due to lower transcription activity as could be shown later with transcription tests in isolated nuclei (van Blokland et al., 1994). The observation was named “co-suppression” but the underlying mechanism remained unknown. In 1997, Metzlaff and colleagues pointed to a role of double-stranded RNA in the initiation of PTGS as they found that the expression of the *chsA* transgene resulted in the formation of double-stranded RNA which initiates PTGS (Metzlaff et al., 1997). Although the first observations were made in plants, the phenomenon of PTGS is not limited to this evolutionary group. Shortly after the discovery in petunia plants, reversible gene silencing in the fungal species *Neurospora crassa* was demonstrated and termed “quelling”. It was achieved by introducing plasmids containing different constructs of the albino-3 gene (*al-3*) or the *al-1* gene which are involved in the biosynthesis of carotenoids and subsequent screening for an albino phenotype (Romano et al., 1992). When cultivating the resulting primary transformants for longer times a phenotypic reversion could be observed indicating that the gene silencing was only transient and not heritable in this model.

Although the biochemical nature of PTGS inducers was assumed to be double-stranded RNA, it was the group of Craig Mello and Andrew Fire who finally proofed this. In 1998, they injected different RNA molecules targeting the non-essential *unc* gene into *Caenorhabditis elegans* and examined the resulting phenotypes (Fire et al., 1998). It could be shown conclusively that double-stranded RNA rather than single-stranded RNA (either sense or anti-sense strand) is a potent inducer of RNAi. This effect was evident in both the injected animals and their progeny arguing for a heritable mechanism in *C. elegans*. Moreover, they demonstrated that even a few molecules of dsRNA were enough to evoke the RNAi phenotype, thereby disproving the model of stoichiometric gene silencing and indicating an amplification mechanism within the worms. This amplification of RNAi leading to systemic silencing was also detected in plants. When grafting a scion of a non-silenced tobacco plant on a beheaded stock plant which was silenced in the *nias2* gene causing chlorosis of the plant, the grafted scion also developed chlorosis (Palauqui et al., 1997). With this experiment, a systemic spreading of the PTGS signals could be shown. Systemic RNAi was also shown for other organisms but not for flies or mammals and it involves a RNA-

dependent RNA polymerase (RdRP) and most likely membrane transport proteins to facilitate whole organism spread (Himber *et al.*, 2003).

First attempts to specifically silence genes in vertebrates and mammalian cell lines using dsRNAs failed (Oates *et al.*, 2000). This was mainly due to the fact that long dsRNA, consisting of more than 30 base pairs activates the mammalian protein kinase PKR (Manche *et al.*, 1992) which leads to a non-specific translation inhibition and eventually to apoptotic cell death (Gil *et al.*, 2000). In a cell-free system of *Drosophila* embryo lysates (Tuschl *et al.*, 1999) it could be demonstrated that long dsRNA is cleaved by an ATP dependent mechanism to RNA fragments of 21-23 nt which act as guiding strands for mRNA cleavage (Zamore *et al.*, 2000). Using the same *Drosophila in-vitro* system, the group of Thomas Tuschl could show that chemically synthesized small inhibitory RNA (siRNA) duplexes targeting specific mRNA sequences are potent inducers of RNAi in these lysates (Elbashir *et al.*, 2001b). This finding highlighted that long dsRNA was not necessarily required for gene silencing. The same group was then able to show that synthesized siRNA molecules of 21 nt length are competent to mediate RNAi in different mammalian cell lines without eliciting non-specific cellular responses as detected with longer dsRNA molecules (Elbashir *et al.*, 2001a). This observation made possible the employment of RNAi in virtually all commonly used laboratory cell lines. Since then significant improvement with respect to delivery of siRNAs, sequence specificity, and large-scale applications of RNAi has been made to answer important scientific questions.

### 1.1.2 The molecular mechanism of RNAi

Evolutionary, the RNAi pathway induced by dsRNA can be seen as a protective mechanism against viral attacks and to maintain genome integrity, possibly threatened by transposon elements. Indeed, the minimum components necessary for cleavage of long dsRNA into siRNA fragments and subsequent degradation of target RNAs are present in essentially all eukaryotic groups, suggesting a development that took place very early in the evolution of eukaryotic species (for overview see (Shabalina *et al.*, 2008).

The RNAi pathway can be divided into two stages: the initiation and the effector stage. During the initiation phase small interfering siRNAs are generated from long dsRNA molecules mediated by the enzyme Dicer. In a next step, these siRNA molecules are introduced into the RNA induced silencing complex (RISC), a high molecular weight protein complex, where the dsRNA fragments are unwound and subsequently bind to their target mRNA in a sequence specific manner to finally facilitate the degradation of the mRNA.

Dicer was identified as a dsRNA-specific RNase-III-type endonuclease with two RNaseIII domains and a dsRNA binding motif (Bernstein *et al.*, 2001). It is conserved structurally and functionally among eukaryotic species. Whereas humans possess only one Dicer protein (Provost *et al.*, 2002), the fruit fly *Drosophila melanogaster* encodes two paralogues, DCR-1 and DCR-2, which are involved in processing miRNAs and dsRNAs, respectively (Lee *et al.*, 2004). For the plant *Arabidopsis thaliana* as much as four Dicer-like proteins (DCL) have been identified so far, with each of them fulfilling different RNA-processing functions (Xie *et al.*, 2004). Dicer produces siRNA fragments of about 21 nt length with 5' phosphates and 2-nucleotide 3' overhangs, a process shown to be ATP-dependent for DCR-2 of *D. melanogaster* (Nykanen *et al.*, 2001), but not for human Dicer (Zhang *et al.*, 2002).

Several proteins have been reported to interact with Dicer at different stages of RNAi. One major group of proteins is the family of PPD (PAZ Piwi domain) proteins. These are highly conserved proteins that can be found in diverse organisms ranging from archae to humans. They possess two characteristic protein domains: a central PAZ domain (named after three

members of this group: Piwi, Ago, and Zwiile) and a C-terminal PIWI domain (Cerutti *et al.*, 2000). The PAZ domain was reported to bind to the 2 nt 3' overhangs of the siRNA molecule, thereby enabling the introduction of the guide siRNA into the RISC (Song *et al.*, 2003, Ma *et al.*, 2004), whereas the PIWI domain is responsible for binding of the PPD proteins to Dicer (Tahbaz *et al.*, 2004). Most research has been performed on the group of PPD proteins named Ago. Ago1 and Ago2 of humans (Martinez *et al.*, 2002) and Ago2 of *Drosophila* (Hammond *et al.*, 2001) were among the first protein components of RISC to be identified during experiments to isolate the ribonucleoprotein structures. The crystal structure of an Ago protein from the archae *Pyrococcus furiosus* was resolved in 2004 and showed similarities to members of the RNase H family (Song *et al.*, 2004). Since RNase H enzymes are responsible for cleaving RNA in a RNA/DNA duplex it was proposed that Ago proteins are responsible for cleaving the target mRNA in the RISC during the stage of guide siRNA/target mRNA duplex formation. The proposed enzymatic activity was named Slicer and in humans this is performed by Ago2 (Meister *et al.*, 2004).

Several other non-PDD proteins were identified to be part of the RISC, many of them with so far unknown functions and the list is still expanding. The role of the *Drosophila* protein R2D2 in RNAi initiation and effector stage has been examined in more detail. It was identified as a dsRNA-binding protein co-fractionating in S2 cell extracts that displayed dsRNA-processing activity (Liu *et al.*, 2003). R2D2 forms a stable complex with Dcr2 and this complex is needed for efficient RISC stimulation. Furthermore, the Dcr2-R2D2 association is fundamental for binding and transfer of siRNA single strands to Ago2 in RISC (Liu *et al.*, 2003). The decision which single strand enters RISC is dependent on thermodynamic differences between the two siRNA strands, with the one whose 5' end is less tightly bound serving as guide strand which is transferred to Ago2 (Schwarz *et al.*, 2003). From this data and accumulating other observations a stepwise model was proposed for long dsRNA-mediated post transcriptional gene silencing in *Drosophila* which is probably also relevant for other species and their respective homologous RNAi proteins (see figure I.1).

**Figure I.1: Schematic overview of the RNAi pathway in *Drosophila melanogaster*.**

This model has been proposed based on several experimental observations. See text for details.

In a first step, Dcr2 forms a complex with R2D2 and maybe additional proteins to bind to long dsRNA. Dicer then cleaves the molecule into siRNA fragments of about 21 nt with characteristic 2 nt 3' overhangs. Both the 3' end of the guide siRNA strand which enters RISC

as well as the 5' end of the non-incorporated strand bind to R2D2. In an ATP-dependent enzymatic step the double-stranded siRNA is unwound by helicase activity and the guide siRNA single strand is transferred from the Dcr2-R2D2 complex to Ago2 to facilitate target mRNA cleavage after complementary base pairing. This cleavage takes place between nt 10 and 11 relative to the 5' end of the guide siRNA (Elbashir *et al.*, 2001b). The cleaved mRNA is then targeted and degraded by cellular nucleases (Orban *et al.*, 2005) resulting in the silencing of gene expression. Subsequently, the RISC can undergo a new enzymatic RNAi cycle (Hutvagner *et al.*, 2002).

### **I.1.3 Applications of siRNA mediated gene knock down**

#### **I.1.3.1 RNAi screens**

Although the precise molecular mechanisms of siRNA-mediated gene silencing as well as other post-transcriptional gene silencing pathways are still matter of intensive research, soon after the first discoveries the enormous potential of specifically knocking down gene expression was recognized. Especially the large scale application of RNAi developed very rapidly and enabled scientists to examine biological events and underlying genetic traits in high-throughput experiments, ending up finally with genome-wide siRNA screens.

Since the beginning of large-scale screening approaches respective scientific publications have been expanded in number and cover virtually every aspect of cellular biology. For example, a genome-wide screen for *Drosophila* cell morphology was performed by Kiger *et al.* (2003). The group constructed a library of long dsRNAs targeting about 1,000 different genes from various functional backgrounds to screen in a 384 well plate format. Using automated microscopy and differential staining they could identify several genes that altered the morphology of either round-shaped S2R<sup>+</sup> cells or flat-shaped Kc<sub>167</sub> cells or both cell types with respect to actin organisation, cell size, and other features (Kiger *et al.*, 2003). A screen conducted by Kamath *et al.* (2003) aimed to functionally analyse the genome of *Caenorhabditis elegans*. Since it is possible to induce RNAi in *C. elegans* by feeding the worms with bacteria expressing long dsRNA molecules (Timmons *et al.*, 1998), they constructed a respective library targeting about 87% of the predicted genome. Gene knock down mediated phenotypes such as sterility or larval lethality were assigned and the responsible genes were grouped to functionally cluster the assayed *C. elegans* genes (Kamath *et al.*, 2003).

To identify genes that are involved in cell division of the human cancer cell line HeLa, a plate-reader based screen was performed (Kittler *et al.*, 2007). The scientists used esiRNAs targeting about 18,000 genes and following knock down cellular DNA content was measured by propidium iodide staining using an Acumen plate reader device. EsiRNAs are enzymatically generated pools of siRNA-like molecules which mediate efficient gene knock down (Yang *et al.*, 2002). Hundreds of genes were identified to influence HeLa cell division although these results have to be judged carefully since HeLa cells, as nearly all laboratory tissue culture cell lines, are already transformed. Thus, it is very likely that genes important for non-transformed cells were not identified within this work.

Also in the field of infection biology large scale RNAi screens have been applied to examine pathogen-host cell interactions by studying the impact of host cell gene knock down on the infection process. One of the first of such screens was a genome-wide RNAi screen performed in *Drosophila* cells to elucidate host cell factors required for *Listeria*

*monocytogenes* intracellular replication (Agaisse *et al.*, 2005). Using automated microscopy and distinct bacterial intracellular phenotypes as read-out, about 200 targets that influenced *Listeria* replication were identified. In a comparable screen, Philips *et al.* (2005) identified CD36 family members as being involved in mycobacterial infection of *Drosophila* cells. Several screens have been published dealing with viral entry and/or intracellular replication, e.g. for hepatitis C virus (Randall *et al.*, 2007), West Nile virus (Krishnan *et al.*, 2008) or Influenza virus (Hao *et al.*, 2008).

In 2007, a kinome siRNA screen for intracellular growth of *Salmonella* Typhimurium was published in which the serine/threonine kinase PKB/Akt1 was reported to be essential for bacterial replication (Kuijl *et al.*, 2007). The screen was performed in MCF-7 cancer cells and analyzed using automated microscopy in 384 well format. The basic idea was to identify host cell targets that could be chemically inhibited to prevent intracellular bacterial replication and the group could show that H-89, a well-known protein kinase A (PKA) inhibitor, was able to decrease *Salmonella* replication. The group claimed that PKA is not the real target of H-89 and in order to identify it they performed a kinase library screen. Although the published primary data did not necessarily point to Akt1 as being a fundamental host cell factor for *Salmonella* infection, it was chosen for further analysis. In subsequent experiments, the Akt1 substrate AS160 was identified to be involved in *Salmonella* growth by repressing the activity of Rab 14 resulting in phagosomal fusion with lysosomes. When AS160 gets inactivated by Akt1 mediated phosphorylation this fusion is inhibited by the activity of Rab 14.

Interestingly, during the screen performed in this work neither Akt1 nor any other kinase or kinase-related protein reported by this group could be identified as affecting *Salmonella* intracellular growth. This will be discussed in detail in the discussion section.

### I.1.3.2 Therapeutic applications

The possibility to specifically degrade RNA by the means of siRNA molecules encouraged scientists to develop therapeutic applications, especially anti-viral and anti-cancer approaches. By using synthetic siRNAs targeting the human immunodeficiency virus (HIV) envelope gene *env*, Park and colleagues (2003) could inhibit viral replication in tissue culture cell lines as well as in activated peripheral blood mononuclear cells (PBMC). Also, inhibition of hepatitis B virus using small hairpin (sh) RNA constructs that targeted different viral components was successful in cell culture and in immunocompetent and –compromised mice (McCaffrey *et al.*, 2003). ShRNAs are retrovirally encoded RNAs that form a siRNA-like duplex by hairpin formation. These shRNAs are then recognized by the RNAi apparatus, thereby inducing target mRNA degradation. Since the retroviral construct is normally integrated into the host genome, a permanent inhibition of a specific gene expression can be achieved.

Several other reports on viral inhibition using RNAi were published, indicating a potential therapeutic strategy (Zhou *et al.*, 2008, Vigne *et al.*, 2009). Nevertheless, the rapid viral mutation rate limits these approaches since strict sequence complementarities are a prerequisite for efficient siRNA mediated gene silencing.

Another potential field of applied RNAi is the therapeutic treatment of cancer diseases. Since it is known that the overexpression of specific genes (oncogenes) favors the development of different forms of cancer, and indeed may serve as tumour markers, it was proposed to use RNAi as a gene therapeutic tool by inhibiting the expression of such oncogenes. It could, for example, be demonstrated that the stable gene silencing of the oncogenic allele K-RasV12 leads to a loss of tumorigenic properties of a mammalian cell line (Brummelkamp *et al.*,

2002). It is thus tempting to hope for the development of cancer-type specific gene therapies based on RNAi.

#### I.1.4 Summary

Since the first experimental discoveries of the siRNA mediated gene silencing strong effort has been made in order to elucidate the molecular mechanism and to develop suitable applications to use RNAi as a cell biological tool. Although the advances in this field are strikingly and have been achieved in comparatively short time, major drawbacks still exist and might remain. These are for example: off-target effects, i.e. the down-regulation of other transcripts than the targeted one, cell toxicity due to transfection reagents, non-specific cellular responses following transfection treatment, and hard-to-transfect cell lines such as immune cells. Nevertheless, the siRNA mediated gene silencing displays a precious tool to study gene function, possibly to combat diseases, and surely to examine host-pathogen interactions from the host cell side.

### I.2 The biology of *Salmonella*

#### I.2.1 Overview

*Salmonella* are Gram negative, rod-shaped, facultative anaerob bacteria belonging to the genus Enterobacteriaceae. They are mostly motile with peritrichous flagella and express different types of adhesins. *Salmonella* are very relevant pathogens of humans and livestock. Especially in under-developed countries with poor sanitary conditions infections with *Salmonella* display a significant health problem. The genus consists of only two species: *Salmonella bongori* and *Salmonella enterica*, the former one being a pathogen of cold-blooded animals such as reptiles. The latter one can be further divided into a large number of different sub-species and serovars as defined by the antigenic composition of their somatic and flagella antigens (see table I.1) (Tindall *et al.*, 2005).

Table I.1

Salmonella species	Subspecies	Important serovars
<i>Salmonella enterica</i>	<i>S. enterica</i> subsp. <i>enterica</i> <i>S. enterica</i> subsp. <i>salamae</i> <i>S. enterica</i> subsp. <i>arizonae</i> <i>S. enterica</i> subsp. <i>diarizonae</i> <i>S. enterica</i> subsp. <i>houtenae</i> <i>S. enterica</i> subsp. <i>indica</i>	Typhi, Typhimurium
<i>Salmonella bongori</i>	none	

Nearly all reported cases of Salmonellosis in humans and livestock are caused by isolates from the *S. enterica* subsp. *enterica* subgroup. In humans, members of this subgroup are the causative agent of different diseases that range from mild, self-limiting gastro-intestinal disorders to severe systemic diseases with significant fatality. Although the systemic, life-

threatening typhoid fever, caused by the *S. enterica* subsp. *enterica* serovars Typhi and Paratyphi, does not play a significant role in industrialized countries, gastro-intestinal Salmonellosis infections are among the most frequently reported infectious diseases in many developed countries. In Germany, non-typhoid Salmonellosis showed an incidence of 67 cases per 100,000 inhabitants in 2007 and was therefore the second most prevalent bacterial infection (RKI: Epidemiologisches Bulletin 2008/16). *Salmonella* infections also constitute a major problem in animal husbandry, mainly by transmitting bacteria with contaminated food or water, while normally the animals are clinically silent.

### 1.2.2 *Salmonella* Typhimurium

*Salmonella* Typhimurium is the causative agent of mild to severe gastro-intestinal disorders and one of the major causes of food-poisoning. In contrast to humans, where *Salmonella* Typhimurium mainly remains extracellular in the gut's lumen, in mice it is capable of breaching the intestinal barrier and eliciting a systemic disease where it primarily targets macrophages. Owing to the strict human specificity of *Salmonella* Typhi, the causative agent of typhoid fever, *Salmonella* Typhimurium serves as a model organism to elucidate general mechanisms of pathogen-host interactions. Utilized in infection models with tissue culture cell lines and in mouse experiments, *Salmonella* Typhimurium is a very important tool for studying the intracellular lifestyle of a pathogen.

#### 1.2.2.1 Attachment and invasion

The initial attachment of *Salmonella* Typhimurium (Stm) to host cells is mediated by a number of different fimbrial adhesins, especially type I fimbriae which have been shown to be important for binding to epithelial cell lines (Boddicker *et al.*, 2002, Althouse *et al.*, 2003). In contrast to *S. Typhi*, where the cystic fibrosis transmembrane conductance regulator (CFTR) was identified to be responsible for binding (Pier *et al.*, 1998), no specific host cell receptor has been determined for Stm yet. It was suggested that cellular membrane components sensitive to trypsin and neuraminidase are involved in bacterial invasion (Finlay *et al.*, 1989), thus arguing for a receptor-like structure. In another report the cholesterol-dependency of invasion was described, indicating that cholesterol-enriched membrane domains, such as lipid rafts, might be necessary for bacterial invasion, probably by serving as a docking station for the translocon component of the bacterial translocation system (Hayward *et al.*, 2005). This would explain the rather unspecific ability of Stm to infect a wide range of different cell lines and host species.

The expression of genes important for the invasion process is mainly regulated by the hyper-invasive-locus A (*hilA*), a transcriptional regulator encoded on a cluster of virulence genes named *Salmonella* pathogenicity island 1 (SPI-1) (Lee *et al.*, 1992, Bajaj *et al.*, 1995). *HilA* expression itself is controlled by environmental signals such as oxygen levels, osmolarity, bacterial growth phase or pH (Bajaj *et al.*, 1996). *HilA* activates the transcription of two important genes, *invF* and *sicA*, which then initiate the expression of several other invasion genes located inside and outside of SPI-1. Therefore, *HilA* constitutes a central regulator in bacterial invasion. As a response to environmental stimuli and controlled by *HilA* a specialized secretion apparatus encoded on SPI-1, the SPI-1 type-III secretion system (SPI-1 T3SS), is formed (Kubori *et al.*, 1998). This T3SS induces the uptake into non-phagocytic cells through the delivery of different effector proteins. It consists of more than 20 proteins and is

evolutionary related to the flagellar export system (see figure I.2). One set of proteins forms a supramolecular structure, referred to as the needle complex, consisting of two rings embedded into the inner and the outer membrane of the bacterium, a rod-like structure connecting the two rings and a filamentous needle connected to the outer ring (Marlovits *et al.*, 2004). At the tip of the needle a translocon complex is formed by the proteins SipB, SipC and SipD which is integrated into the host cell membrane to facilitate the translocation of bacterial proteins (Collazo *et al.*, 1997, Scherer *et al.*, 2000). In the absence of any of these components, effector proteins are unable to cross the host cell membrane and, instead, are

**Figure I.2: Schematic illustration of the SPI-1 T3SS.**

For clarity reasons only the main components are depicted. See text for details. IM: inner bacterial membrane, OM: outer bacterial membrane.

Adopted from Kimbrough and Miller, 2002

secreted into the medium. The secretion of effector proteins is mediated by a consensus sequence within the N-terminus of these proteins (Miao *et al.*, 2000). Most of these effectors are stabilized by chaperones which direct them to the secretion apparatus (Bronstein *et al.*, 2000, Tucker *et al.*, 2000). InvC, an ATPase located at the base of the needle complex, then drives the chaperone release and transport of proteins through the T3SS (Eichelberg *et al.*, 1994, Akeda *et al.*, 2005). Ten different effector proteins have been identified so far to be delivered via the SPI-1 encoded T3SS. Several of them (SipA, SipC, SopB, SopE, SopE2, and SptP) are either directly or indirectly involved in the sophisticated manipulation of the host cell actin cytoskeleton to facilitate entry into the cell. SopE and the highly similar SopE2, for instance, are guanine nucleotide exchange factors (GEF) for Rac1, Cdc42, and RhoG, thus activating these proteins which are critical for actin physiology (Hardt *et al.*, 1998, Stender *et al.*, 2000, Patel *et al.*, 2006). The precise function of SopB, a versatile protein with phosphatase activity on different phosphatidyl-inositol phosphate (PIP) species, is not yet understood in every detail but it contributes to *Salmonella* invasion by altering the PIP(4,5)<sub>2</sub> levels at the plasma membrane (Terebiznik *et al.*, 2002) and by indirectly activating RhoG through the stimulation of the exchange factor SGEF (Patel *et al.*, 2006). The activation of the host's small GTPases leads to the recruitment of the Arp2/3 complex via the WAVE and the WASP signaling pathways resulting in the induction of membrane ruffles (Criss *et al.*, 2003, Shi *et al.*, 2005). Although the recruitment of the Arp2/3 complex seems to be

essential for *Salmonella* invasion, its role in actin assembly during invasion is contradictory (Unsworth *et al.*, 2004).

Two other SPI-1 T3SS translocated effector proteins contribute to the induction of actin rearrangements, namely SipA and SipC. SipA directly binds to actin, induces its polymerisation and subsequently stabilizes actin filaments (Zhou *et al.*, 1999, Lilic *et al.*, 2003). SipC has been demonstrated to bundle actin *in-vitro* which was also confirmed in cell culture experiments with microinjected purified SipC (Hayward *et al.*, 1999). However, since it possesses a central hydrophobic region it was speculated that SipC acts from host cell membranes rather than from the cytosol. Additionally, it was shown that SipC also interacts with host cell keratins, components of the intermediate filament structure (Carlson *et al.*, 2002). Thus, SipC probably connects membrane-located keratins with actin filaments to promote the stability of the induced membrane protrusions. In another report it was described that SipA can enhance the activity of SipC, which indicates a cooperative action between these two proteins (McGhie *et al.*, 2001). The induced actin rearrangements leading to engulfment and uptake of adhesive *Salmonella* are counteracted by the effector protein SptP to ensure recovery of the cytoskeleton after invasion. SptP was shown to be able to reverse the GEF function of SopE on Rac1 and Cdc42 by preferentially binding to Rac1-GTP and Cdc42-GTP and exerting a GTPase activity, which downmodulates Rac1 and Cdc42 (Fu *et al.*, 1999). In a subsequent study, the fine-tuning between SopE and SptP activities was shown to be dependent on the different half-life of these proteins. Although both proteins are translocated in equal amounts, SopE is rapidly degraded by the host cell proteasome whereas SptP remains inside the cytosol for longer times. This enables SptP to reverse the SopE induced actin rearrangements (Kubori *et al.*, 2003).

#### **1.2.2.2 Phagosome formation and intracellular replication**

Once *Salmonella* entered the host cell it resides in a phagosome-like compartment called the *Salmonella*-containing vacuole (SCV), that was first described by Finlay and Falkow (1988), where the bacteria start to replicate after a lag period of about 3-4 hours (see figure 1.3). The formation of the SCV and its subsequent development along the phagosome-maturation pathway has been the object of intensive studies, yet with partially conflicting data. This is often attributed to the different pathogen-cell culture models used. It has been shown that the SCV transiently interacts with the early endocytic and the recycling pathway and rapidly acquires and loses respective markers such as early endosome antigen-1 (EEA1) and the transferrin receptor (TfR) (Steele-Mortimer *et al.*, 1999) or Rab11 (Smith *et al.*, 2005), respectively. Scott *et al.* (2002) could show that the recruitment of EEA1 is dependent on PI3P at the vacuole, and probably EEA1 is involved in the homotypic fusion of early SCVs to generate larger vacuoles (Mills *et al.*, 1998). Shortly after invasion, early endosomal markers are replaced by those of late endosomes like Rab7 and lysosomes such as LAMP-1 and vATPase (Steele-Mortimer *et al.*, 1999). The GTPase Rab7 replaces Rab5 to promote early to late endosome transition along the endocytic traffic of phagosomes (Rink *et al.*, 2005) and initiates the fusion with lysosomal compartments by recruiting the effector protein RILP. RILP interacts with the dynein-dynactin motor complex to facilitate transport of endosomes towards the minus-end of microtubules to lysosomes (Cantalupo *et al.*, 2001, Jordens *et al.*, 2001). It has been reported that the recruitment of Rab7 to SCV membranes is essential for a proper maturation of the SCV (Meresse *et al.*, 1999) and, indeed, in this work further evidence is presented on the essential role of Rab7 on *Salmonella* intracellular growth. There is contradictory data whether or not the SCV fuses with lysosomes. Although some

lysosomal markers are acquired during the maturation of the SCV, such as LAMP-1 (Garcia-del Portillo *et al.*, 1995) and the vacuolar ATPase (Steele-Mortimer *et al.*, 1999), others such as cathepsin D and mannose-6-phosphate-receptors could not be detected (Hashim *et al.*, 2000). *Salmonella* senses the intracellular milieu by different two-component systems with the PhoP/Q system being the best studied one. The SCV is poor in ions like  $\text{Fe}^{2+}$  and  $\text{Mg}^{2+}$  and slightly acidic as determined by respective reporter constructs and microarray studies (Garcia-del Portillo *et al.*, 1992, Rathman *et al.*, 1996, Martin-Orozco *et al.*, 2006, Hautefort *et al.*, 2008). The low magnesium concentration and probably also the low pH is sensed by

**Figure I.3: Maturation of the *Salmonella*-containing vacuole (SCV).**

Following entry into the host cell, the newly formed SCV interacts with the endocytic pathway and acquires certain specific endosomal markers whereas others, especially lysosomal proteins, are avoided from the vacuole. This suggests an inhibition of lysosomal fusion with the SCV, controlled by the bacterium. See text for further details.

Taken and modified from Bakowski *et al.* (2008).

the global regulator system PhoP/Q (Groisman, 2001, Garcia Vescovi *et al.*, 1996, Chamnongpol *et al.*, 2003) which then activates the transcription regulator PhoP. PhoP is responsible for the expression of a large number of virulence genes to promote intracellular survival and respective *Salmonella* mutants are strongly impaired in their virulence (Galan *et al.*, 1989, Miller *et al.*, 1989). Under the control of the PhoP/Q regulon and another transcriptional activator, OmpR, genes are expressed encoding a second T3SS located on SPI-2 which translocates effector proteins across the vacuolar membrane into the host cell cytosol (Shea *et al.*, 1996). The SPI-2 T3SS has been shown to be essential for virulence and the secreted effector proteins contribute to the intracellular survival of *Salmonella* by altering host cell processes. So far, about twenty different proteins have been described as being delivered by the SPI-2 T3SS, although the precise function and possible host cell targets are largely unknown (see figure I.4). Additionally, it is not clear whether all of these proteins play an essential role in survival since single gene knock out mutations do not impair growth *in-vivo* to the same extent as when deleting the entire SPI-2 T3SS, thus arguing for non-essential proteins and/or a functional redundancy among effector proteins. One of the best characterized SPI-2 effector is SifA, a protein that gets modified at the C-terminus by host cell enzymes after translocation to facilitate SCV membrane anchorage (Reinicke *et al.*, 2005, Boucrot *et al.*, 2003). SifA has been identified as being responsible for

the generation of filamentous, LAMP-1 enriched membrane structures that protrude from the SCV along microtubules and were termed *Salmonella* induced filaments (Sif) (Garcia-del Portillo *et al.*, 1993, Stein *et al.*, 1996, Brummell *et al.*, 2002). *SifA* mutants are impaired in replication inside macrophages due to the disruption of the vacuolar membrane and release of bacteria into the cytosol, indicating that SifA ensures the integrity of the SCV membrane (Beuzon *et al.*, 2000, Brummell *et al.*, 2001a). Using a yeast-two-hybrid approach Boucrot *et al.* (2005) could identify a human protein of unknown function as an interacting partner which was named SKIP (*SifA* and *kinesin*-interacting *pr*otein) due to the fact that SifA controls the

**Figure I.4: Modulation of the SCV and involved SPI2 effectors.**

The SPI2 encoded T3SS delivers several effector proteins across the SCV membrane into the host cell cytosol where they fulfil different functions to enable intracellular replication. (Haraga *et al.*, 2008)

activity of the plus-end microtubule motor kinesin via this protein. This process is supposed to prevent uncontrolled elongation of Sifs which is partly induced by the action of another SPI-2 effector, PipB2, which has been shown to redistribute endosomal vesicles to the cell periphery in overexpression experiments (Knodler *et al.*, 2005b). Henry *et al.* (2006) identified PipB2 as a linker for kinesin to the SCV membrane, thus having a function oppositional to SifA. This was also speculated for the effector SseJ since the deletion of the respective gene was able to rescue the inhibitory effects on Sif formation in a  $\Delta sifA$  background (Ruiz-Albert *et al.*, 2002) and cells infected with a *sseJ* mutant strain exhibit increased numbers of Sifs (Birmingham *et al.*, 2005). SseJ is an effector protein sharing similarity to the family of GDSL lipases (Akoh *et al.*, 2004) and deacylase and cholesterol acyltransferase activity has been described for this protein (Ohlson *et al.*, 2005, Nawabi *et al.*, 2008, Lossi *et al.*, 2008). Therefore it was speculated that SseJ contributes to the lipid modification of the vacuolar membrane which might enable Sif curvatures or the generation of membrane microdomains involved in vesicle docking. So far the roles of the effector proteins SseF and SseG have not been clarified completely, since they have been allocated to endosome aggregation, microtubule bundling, recruitment of exocytic vesicles, and intracellular positioning of the SCV (Guy *et al.*, 2000, Kuhle *et al.*, 2004, Kuhle *et al.*, 2006, Salcedo *et al.*, 2003). Taken together it becomes clear that intracellular *Salmonella* heavily modify the SCV in order to promote survival and replication. Through a concerted action of several translocated effector proteins with so far only incompletely understood functions, *Salmonella* builds up membranous Sifs which may have different functions, for example recruitment and fusion of endocytic and/or exocytic vesicles for nutrient supply and

modification of the SCV membrane to form microdomains involved in docking of vesicles or as platforms to influence host cell signaling. Moreover, a stable vacuolar boundary is important for *Salmonella* to avoid the harmful cytosolic environment of the host cell, especially the one of phagocytes which efficiently kills pathogens.

### 1.2.2.3 Impact on host cell signaling

Infections with *Salmonella* Typhimurium elicit pronounced enteric inflammation reactions accompanied by diarrhoea. The molecular mechanisms underlying this are not fully understood yet, but they are doubtlessly multi-factor events with both pathogen and host properties contributing. Additionally, signaling events connected to inflammation observed in tissue culture cell models may not reflect the *in-vivo* situation which is examined in animal models of enteritis.

The SPI-1 effector dependent stimulation of Rac1 and Cdc42 also activates mitogen activated protein kinases (MAPK) that leads to nuclear responses of the host cell, such as the activation of the transcription factors c-Jun (Hobbie *et al.*, 1997, Chen *et al.*, 1996a) and nuclear factor kappa B (NFkB) as determined by IL-8 secretion of epithelial cells (Eckmann *et al.*, 1993, Hobert *et al.*, 2002). Also other SPI-1 effector proteins have been identified to induce inflammatory reactions in different infection models (Jones *et al.*, 1998, Chang *et al.*, 2007). In a polarized epithelial cell culture model SopB, SopE and SipA dependent disruption of tight junctions was reported (Boyle *et al.*, 2006). Additionally, bacterial flagellin, the main component of flagella, recognized by host cell toll-like-receptor 5 (TLR5) can induce inflammatory responses (Tallant *et al.*, 2004). *In-vivo*, secretion of IL-8 leads to the attraction of polymorphonuclear leukocytes (PMN) and inflammation whereas SopB and SopA mediated tight junction disruption causes ion effluxes and diarrhoea.

Infections with *Salmonella* Typhimurium often result in profound gastro-intestinal disorders, at least partly due to the induction of inflammatory responses described. In order to turn back potentially harmful host responses and to avoid rapid clearance from the gut owing to massive diarrhoea, *Salmonella* Typhimurium has evolved strategies to downmodulate pro-inflammatory signaling cascades. A major aspect is the inhibition of NFkB dependent gene expression. SspH1 is an effector protein which has been described to interact with the host cell kinase PKN1 (Haraga *et al.*, 2003, Haraga *et al.*, 2006), a kinase involved in the NFkB and JNK (c-Jun N-terminal kinase) signaling pathway (Kato *et al.*, 2008) and this is proposed to inhibit NFkB activity, although the authors failed to conclusively proof this. NFkB inhibition was also shown for the secreted effector SseL (Le Negrate *et al.*, 2008). Additionally, SpvC, a factor encoded on a virulence plasmid present in some *Salmonella* serovars (Jones *et al.*, 1982), has been reported to inhibit the MAPKs ERK (extracellular signal-regulated kinase) and JNK. This is achieved via its phosphothreonine lyase activity, an enzymatic property similar to that seen for the *Shigella* effector protein OspF (Mazurkiewicz *et al.*, 2008, Li *et al.*, 2007). JNK is also targeted to downmodulate host immune responses by another effector, AvrA, translocated via the SPI-1 T3SS (Jones *et al.*, 2008). In contrast to the *Yersinia* effector YopJ which was reported to inhibit different MAPKs (Orth *et al.*, 1999), AvrA seems to specifically block JNK signaling.

Thus, taking into account the numerous effector proteins that were described as being able to downregulate pro-inflammatory pathways it emerges that *Salmonella* Typhimurium aspires to control the innate immune response of the host in order to prevent excessive tissue inflammation. This might help the bacteria to colonize the gut epithelium for prolonged times.

#### 1.2.2.4 *Salmonella* and cell death

Apoptosis, one form of programmed cell death, is a complex, tightly regulated process of self-elimination which is essential for normal development, tissue homeostasis and also for repelling infections. It was first described by Kerr et al. (1972) and since then ever increasing knowledge of different apoptosis pathways and their regulation has been accumulated. Apoptosis, as a controlled, non-inflammatory cell death, can be distinguished from necrosis, which leads to the burst of cells and the release of highly inflammatory cytosolic contents into the tissue, although this strict classification has been weakened and several mixed-classes of cell death have been defined (Kroemer *et al.*, 2009). In order to combat intracellular infections, apoptosis constitutes a major strategy to prevent spread of infection. Therefore, the inhibition of host cell apoptosis is crucial for several intracellular pathogens in order to endure the replication niche. On the other hand, induction of apoptosis at the right time of the infection cycle might promote the systemic dissemination and thereby exhibits an attractive route for many pathogens.

The interactions of intracellular *Salmonella* with the host cell's death machinery had long been poorly understood. However, recent studies more and more reveal the complex signaling underlying this process. Initially, *Salmonella* induced apoptotic cell death was described for the macrophage-like cell lines J774A.1 (Chen *et al.*, 1996b) and RAW264.7 (Monack *et al.*, 1996). In the study with J774 cells, the majority of infected macrophages showed the characteristic apoptotic morphology very early during infection. It could be demonstrated that this process was dependent on active invasion since stationary phase bacterial cultures displayed only minor cytotoxic activity. Later, it could be shown that the rapid macrophage killing is dependent on the bacterial protein SipB which is a component of the SPI1-T3SS and that SipB binds to Caspase-1 which causes release of pro-inflammatory IL-1 $\beta$  and IL-18 (Hersh *et al.*, 1999, Monack *et al.*, 2001). Due to the fact that this form of cell death displays characteristics of both apoptosis and necrosis, it has recently been termed pyroptosis (Fink *et al.*, 2007). Most recently, the inflammasome protein Ipaf was identified to play an important role in *Salmonella*-induced pyroptosis (Fink *et al.*, 2008). Although the impact of SipB on host cell death has been emphasized by several other reports, the precise cellular mechanism is still under discussion since it was also described to induce mitochondria-dependent autophagy (Hernandez *et al.*, 2003). Moreover, SipB independent killing during the course of infection has been described (Santos *et al.*, 2001). Additionally, the route of entry into macrophages seems to be important for the cytotoxic effects (Forsberg *et al.*, 2003), which might resemble different stages of the *in-vivo* infection, namely the disseminating infection with actively invading bacteria, accompanied by clinical symptoms, and the silent, persistent stage of mainly phagocytosed bacteria.

Remarkably little is known about apoptosis pathways in *Salmonella* infected epithelial cells. Lundberg et al. (1999) reported that different epithelial cell lines infected with *Salmonella* Typhimurium did not undergo cell death at an early time point as compared to macrophages. Since most epithelial cell lines are derived from carcinoma tissues they often do not go into apoptosis easily, thus, this result has to be assessed carefully. Apoptosis of the colon cancer cell line HT-29 was shown after longer infection with *Salmonella* (Kim *et al.*, 1998), although a significant proportion of the cells also showed features of necrosis. Recently, the *Salmonella* effector SopB, translocated via the SPI1-T3SS, was shown to protect epithelial cells from apoptosis by activating the pro-survival kinase PKB/Akt1 (Knodler *et al.*, 2005a). Owing to the few reports a concluding determination whether *Salmonella* induces or inhibits epithelial apoptosis can not be made. Most likely this depends on the stage of

infection, the tissue type or host responses and *Salmonella* is potentially capable of controlling both directions.

### 1.2.3 Summary

*Salmonella* Typhimurium is a Gram negative, facultative intracellular pathogen which has the capacity to infect a wide range of host species and has become an object of intensive scientific studies with regard to pathogen-host cell interactions. It induces its uptake into non-phagocytic cells by the delivery of effector proteins via a sophisticated T3SS. After uptake, the bacteria reside in a phagosome-like compartment which undergoes maturation resembling the endocytic pathway to a certain extent. Throughout the whole infection cycle the bacteria remain inside the vacuolar compartment, termed the *Salmonella*-containing vacuole, which is actively remodelled by the pathogen and where replication is taking place. A second T3SS is expressed intracellularly and a plethora of effector proteins is delivered across the vacuolar membrane into the host cell's cytosol. Although the precise function of the majority of these effector proteins is unknown it is tempting to speculate that they serve to interact with host cell factors in order to control their functions during the establishment of the intracellular replication niche. Thus, *Salmonella* is interacting at several stages of the infection with its host cell in order to facilitate entry, to replicate inside a modified phagosome, and to manipulate host cell signaling pathways to prevent degradation. The whole spectrum of these interactions is still far away from being deciphered.

### 1.3 Goals of this study

Intracellular pathogens are in close contact to their host cells and rely on their cellular machinery to assure a successful infection. During the evolution of host-pathogen interactions, a complex network has developed with both the host and the pathogen contributing. The identification of host cell functions which are essential for these interactions is crucial for the understanding of the mechanisms underlying pathogenicity and moreover serves to gain deeper insights into important host cell pathways.

The aim of this work was to elucidate host cell factors that affect the intracellular growth of the Gram negative pathogenic bacterium *Salmonella* Typhimurium. For this purpose, a large scale high-throughput RNAi screen should be established and performed using a commercial human kinome-wide siRNA library. Kinases display central regulators of a plethora of cellular processes and are therefore likely targeted by intracellular pathogens to subvert host cell functions. In order to screen a large set of siRNAs a high-throughput system had to be established to automate critical steps such as the transfection of the cells or the plate measurement. Therefore, a flow cytometry based screening assay should be developed using a bacterial reporter strain to monitor *Salmonella* intracellular replication and metabolic activity upon host cell gene knock down. The set-up of a semi-automatic screening assay was intended to be achieved with the help of the flow cytometry device FACS Calibur. The primary data from the screening experiments should be validated with additional siRNA sequences to omit false positive candidate genes from further analysis. The final goal was to functionally characterize host cell genes for their role in *Salmonella* Typhimurium infection.

## II Materials and methods

### II.1 Chemicals

All chemicals were purchased from Roth (Karlsruhe), Sigma-Aldrich (Steinheim) or Merck (Darmstadt) if not stated otherwise.

### II.2 Buffers, solutions, and media

#### 10x PCN buffer

0.8 M	MOPS-KOH (pH 7.4)
0.04 M	tricine
0.5 M	NaCl
2.76 mM	K <sub>2</sub> SO <sub>4</sub>

#### PCN medium

1 x	PCN buffer
0.01 mM	FeSO <sub>4</sub>
15 mM	NH <sub>4</sub> Cl
0.5 µM	CaCl <sub>2</sub>
0.4 % or 0.2 %	glucose or arabinose [w/v]
10 mM	MgSO <sub>4</sub>
1.25 mM	potassium phosphate buffer pH7.4
0.01 %	casein [w/v]

#### 10x TBS

200 mM	Tris base
1.4 M	NaCl

adjusted to pH 7.4

#### 1x TBS-T

0.1 % [v/v] Tween 20 in 1x TBS

#### 10x SDS running buffer

247 mM	Tris base
1.9 M	glycin
35 mM	sodiumdodecyl sulphate (SDS)

#### TBE

890 mM	Tris base
890 mM	boric acid
20 mM	EDTA-NA <sub>2</sub>

adjusted to pH 7.4

**Transfer buffer**

25 mM	Tris-HCl pH 8.5
190 mM	glycine
10%	methanol [v/v]
0.1%	SDS [w/v]

**RIPA buffer**

20 mM	Tris-HCl, pH 7.5
150 mM	NaCl
0.5%	NP-40 [v/v]
0.5%	Triton X-100 [v/v]

**Stripping buffer**

68 mM	Tris-HCl, pH 7.5
2%	SDS [w/v]
0.8%	$\beta$ -mercaptoethanol [v/v]

**LB medium**

10 g	Bacto tryptone (BD, Franklin Lakes, NJ, USA)
5 g	Bacto yeast extract (BD, Franklin Lakes, NJ, USA)
5 g	NaCl

ad 1 L with ddH<sub>2</sub>O  
adjusted to pH 7.4

for plates 1.5% (w/v) agar was added

**LB high salt medium**

LB medium with 17.5 g/L NaCl (i.e. 0.3 M)

**4% paraformaldehyde (PFA)**

**II.3 Technical equipment**

For this work, facilities equipped with state-of-the-art laboratory devices were used.

**II.4 Plasmids**

The following plasmids were used in this study. They were maintained in *E. coli* DH5α -80°C glycerol stocks or as midi prep samples at -20°C.

Table II.1: Plasmids used in this study

plasmid	description	source	strain collection N°
pACYC177	cloning vector / AmpR / KanR	Chang and Cohen, 1978 / in-house	H2678
pBAD18	arabinose inducible expression vector / AmpR	Guzman et al., 1995 / in-house	H3125
pFPV25.1	constitutive expression of GFPmut3 / AmpR	Valdivia and Falkow, 1996 / kindly provided by M.	H3892

pFPVmCherry	constitutive expression of mCherry / AmpR	Hensel, Erlangen kindly provided by O. Steele-Mortimer	H3893
pRSET-B mCherry	T7 promoter driven expression of mCherry / template for mCherry PCR / AmpR	Shaner et al. 2004, kindly provided by Tsien Labs, USA	H3894

pOR26	arabinose inducible expression of mCherry / AmpR	this study	H3812

## II.5 Oligonucleotides, small inhibitory RNAs (siRNAs), and antibodies

All oligonucleotides (“primers”) used in this study were synthesized by Invitrogen (Karlsruhe).

Table II.2: Oligonucleotides used in this study

oligonucleotide	sequence (5' → 3')	function
FP_new-F	GCTCTAGATTTAAGAAGGAG ATATACATATGGTGAGCAAG GGCGAGGAG	5' PCR primer for mCherry amplification (5' XbaI restriction site)
FP_new-R	CTCTCAAGCTTATTACTTGTA CAGCTCGTCCA	3' PCR primer for mCherry amplification (3' HindIII restriction site)
pACYC BamHI 5'	GGAAGGTGATGTCATTCTGG	5' sequencing primer for pOR25 quality check
pACYC BamHI 3'	GGCAATACTGAGCTGATGAG	3' sequencing primer for pOR25 quality check
pBAD18 5' MCS	AGATTAGCGGATCTACCTG	5' sequencing primer for pOR26 quality check
pBAD18 3' MCS	CACTTCTGAGTTCGGCATGG	3' sequencing primer for pOR26 quality check

All siRNA oligonucleotides were synthesized by Qiagen (Hilden), except the Rab7A sequences which were synthesized by Dharmacon (Lafayette, CO, USA). After testing the Rab7A sequences, the Rab7A\_2 siRNA was synthesized by Qiagen according to the sequence information provided by Dharmacon.

Table II.3: Small inhibitory RNA (siRNA) oligonucleotides used in this study

siRNA	target gene	siRNA target sequence	remarks
Allstars	none	not available (property of Qiagen)	neutral control
PLK1	polo-like kinase 1 (Drosophila)	CCGGATCAAGAAGAATGAATA	toxic control
Rab7A_1	RAB7A, member RAS oncogene family	AACTAGATAGCTGGAGAGATG	inhibitory control
Rab7A_2	RAB7A, member RAS oncogene family	AAGTACAAAGCCACAATAGGA	inhibitory control
Rab7A_3	RAB7A, member RAS oncogene family	AAAAACGGAGGTGGAGCTGTA	inhibitory control
Rab7A_4	RAB7A, member RAS oncogene family	AACGAATTCCTGAACCTATC	inhibitory control
MKK7_10	mitogen-activated protein kinase kinase 7	CCCTTAGACGCTTGAGAATAA	
MKK7_13	mitogen-activated protein kinase kinase 7	CTGCGCTGAGAAGCTCAAGAA	
PLA2_1	phospholipase A2, group IVA	AACAAGGAGTTTCTAAGTAAA	
PLA2_2	phospholipase A2, group IVA	TCCCATGACAACCTGGATTAA	

Primary antibodies for immunoblotting were diluted in TBS-T buffer containing 3% [w/v] bovine serum albumine (BSA), fraction V, and stored at -20°C for multiple uses. Primary antibodies for immunofluorescence were diluted antibody-specific in 0.1 % [w/v] BSA/PBS for single use. Secondary antibodies for immunoblotting were diluted 1:2000 (anti-rabbit) or 1:3000 (anti-mouse) in 1x TBS-T, 5% [w/v] dry milk powder. Secondary antibodies for immunofluorescence were diluted 1:150 in 0.1 % [w/v] BSA/PBS.

Table II.4: Antibodies used in this study

antibody	supplier and cat. N°	species	application
β-actin	Sigma, A5441	monoclonal mouse	immunoblotting

Rab7A	Sigma, R8779	monoclonal mouse	immunoblotting
MKK7	Cell Signaling, 4172	polyclonal rabbit	immunoblotting
cPLA2	Cell Signaling, 2832	polyclonal rabbit	immunoblotting
P-cPLA2 (Ser505)	Cell Signaling, 2831	polyclonal rabbit	immunoblotting
LAMP-1	BD Biosciences, 555798	monoclonal mouse	immunofluorescence
bacterial Hsp60	Alexis, ALX-804-071	monoclonal mouse	immunoblotting
anti-mouse	GE Healthcare, NXA931	sheep	secondary Ab immunoblotting
anti-rabbit	GE Healthcare, NA934	donkey	secondary Ab immunoblotting

## II.6 Cell biological methods

### II.6.1 Cell lines and cultivation

Cell lines used in this study are described in table II.5. The cells were routinely maintained in RPMI 1640 (Gibco/Invitrogen, Karlsruhe), supplemented with 10% heat-inactivated fetal calf serum, L-glutamine and 25 mM HEPES buffer (i.e. **RPMI full medium**) at 37°C with 5% CO<sub>2</sub> in a humidified temperature-stable cell culture incubator. For longer maintenance, medium was replaced every two to three days and the cells were passaged if appropriate using trypsin detachment.

Table II.5: Mammalian tissue culture cell lines used in this study

cell line	origin	source or reference
HeLa	cervical	DSMZ N° ACC57, obtained from ATCC CCL-2
HT-29	colonic	DSMZ N° ACC299
HEp-2	HeLa contaminant	ATCC CCL-23
Hec1b	endometrial	HTB-113
HepG2	hepatic	DSMZ N° ACC180

### II.6.2 Bacterial strains

The *Salmonella enterica* subsp. *enterica* serovar Typhimurium (*Salmonella* Typhimurium) wildtype strain 12023 was utilized for infection experiments. Expression of different fluorescent proteins was facilitated by plasmid transformation (see table II.1). Cloning experiments were performed with the *Escherichia coli* laboratory strain DH5α.

Table II.6: Bacterial strains used in this study

strain	genotype	source or reference	strain collection N°
<i>S. Typhimurium</i> 12023	wildtype	NCTC 12023 (ATCC 14028)	X102
<i>E. coli</i> DH5α	F <sup>-</sup> , φ80dlacZΔM15, Δ(lacZYA-argF)U169, <i>deoR</i> , <i>recA1</i> , <i>endA1</i> , <i>hsdR17</i> (rk <sup>-</sup> , mk <sup>+</sup> ), <i>phoA</i> , <i>supE44</i> , λ <sup>-</sup> , <i>thi-1</i> , <i>gyrA96</i> , <i>relA1</i>	in-house	E248

### II.6.3 Preparation of bacterial glycerol stocks

For long-term storage of bacteria, glycerol stocks were prepared by mixing 600 μL of an overnight LB culture of the strain with 300 μL of sterile glycerol in cryotubes. The stocks were stored at – 80°C.

## II.6.4 Preparation and transformation of electro-competent bacteria

In order to transform bacteria with DNA, electro-competent bacteria were prepared freshly before use. An overnight LB culture was diluted 1:100 in fresh, pre-warmed medium and grown until OD<sub>600</sub> of 0.5. The bacterial culture was cooled down on ice for 30 min and all subsequent steps were performed at 4°C. The bacteria were pelleted and washed three times in a small volume of pre-chilled ddH<sub>2</sub>O to achieve a thick, dense solution of bacteria. 50 µL of electro-competent cells were mixed with the DNA and transferred to a pre-chilled Eppendorf tube. The mixture was incubated on ice for 30 min and then transferred to a pre-chilled electroporation cuvette (peqlab, Erlangen). Electroporation was performed under conditions indicated below (see table II.7) in a Gene Pulser electroporator (BioRad, Hercules, CA, USA). 1 mL of warm (37°C) LB medium was added to the cuvette, the mixture was transferred to an Eppendorf tube and incubated at 37 °C, 200 rpm for 60 min to allow recovery of the bacteria and expression of resistance genes. Bacteria were plated at different concentrations on selective agar plates to screen for positive clones.

Table II.7: Electroporation conditions

species	voltage [kV]	resistance [Ohm]	capacity [µF]
<i>Salmonella Typhimurium</i> 12023	2.5	600	25
<i>Escherichia coli</i> DH5α	1.6	200	25

## II.6.5 Bacterial infection of mammalian cell lines

The infection of mammalian cells with *Salmonella Typhimurium* was performed based on the infection protocol described by Steele-Mortimer et al. (1999) with minor changes.

Two days before infection a bacterial culture was streaked from the frozen stock on a selective LB agar plate. The next day, an overnight bacterial culture was prepared by inoculating 5 mL of selective LB high-salt medium with one colony from the agar plate. The overnight culture was incubated at 37°C and 200 rpm for 16-20 hours and then diluted 1:33 in fresh, pre-warmed (37°C) selective LB high-salt medium for a further incubation of 3,5 h. A part of the culture was transferred to 1.5 mL Eppendorf tubes and pelleted in an Eppendorf table top centrifuge at 20,000 x g for 1 min. The pellet was washed once with PBS (RT) and resuspended in RPMI full medium (37°C). In order to infect the cells with the aspired MOI, the bacterial culture was diluted according to the following assumption:

$$\text{OD}_{600} \text{ of } 1 \approx 1.5 \times 10^9 \text{ cfu/mL}$$

Additionally, the volume of infection solution of the respective plate format was taken into account (see table II.8). To infect cells with the bacterial infection solution, the cell culture medium was aspirated and a plate format specific volume of infection solution was added to the wells. Plates were centrifuged in a Heraeus multifuge 3 S-R (DJB Labcare, Newport Pagnell, UK) at 700 rpm and RT for 5 min to ensure a synchronized infection and incubated at 37 °C with 5% CO<sub>2</sub> in a humidified cell culture incubator to allow invasion. The cells were washed twice with PBS (RT) 60 min p.i. and remaining extracellular bacteria were killed by addition of killing medium (RPMI full medium with 100 µg/mL gentamicin) for 60 min. For the remaining infection period, the antibiotic concentration was lowered to 20 µg/mL.

For arabinose-induced expression of mCherry, cells were washed twice with PBS (RT) and induction-medium was added to the samples (RPMI full medium + 20 µg/mL gentamicin + 0.2% [w/v] L-arabinose) for the desired period of time.

Table II.8: Cell plate formats and volume of infection solution

cell plate format (well)	volume of infection solution [µL]	type of pipette used
96	50	automatic 8 channel
24	500	manual
12	1000	manual
6	1000	manual

## II.6.6 Gentamicin protection assay

For the enumeration of intracellular bacterial replication, the gentamicin protection assay (gentamicin assay) was performed. Cells were infected as described and extracellular bacteria were killed with gentamicin. At the desired time-points, cells were washed twice with PBS (RT) and then lysed by adding 0.5% [v/v] triton X-100 in PBS to the wells. The lysates were transferred to 1.5 mL Eppendorf tubes. Serial dilutions of the lysates were prepared by diluting 1:10 in PBS and 100  $\mu$ L of the appropriate dilution were plated on agar plates (with antibiotics, if needed). The plates were incubated at 37°C until bacterial colonies were visible and the colonies were counted to calculate intracellular bacteria. The replication rate was determined by forming the ratio of two different time points.

## II.6.7 Measurement of cPLA2 enzymatic activity

In order to detect the enzymatic activity of cPLA2 in HeLa cells a specific substrate (PED6, Molecular Probes) was used which is taken up by the cells and is cleaved predominantly by activated cPLA2. Thereby turns into a fluorescent compound that can be monitored with the FACS Calibur. HeLa cells were either infected as described or left uninfected. At the respective time-point cells were washed and PED6 (5  $\mu$ M) was added in complete medium to the cells for 60 min. Cells were washed thoroughly with PBS, trypsinized and resuspended in PBS for FACS analysis. Excitation = 488 nm; Emission = 530 nm (FL-1).

## II.6.8 Transfection of mammalian cells with small inhibitory RNA (siRNA)

The RNA interference technique was applied to specifically inhibit the translation of eukaryotic genes. Different experimental procedures were used for 12 well format transfections for single knock-down experiments or for 96 well format large scale RNAi experiments (screening).

### II.6.8.1 Transfection in 12 well format

Cells were trypsinized, counted in a Neubauer chamber and seeded at a density of  $1 \times 10^5$  cells/well the day before transfection. For each siRNA to transfect a mixture was prepared and the supernatant was aspirated from the wells. 600  $\mu$ L of fresh, pre-warmed (37°C) RPMI full medium was added before the dropwise apposition of the transfection mixture. The cells were incubated at 37°C with 5% CO<sub>2</sub> in a humidified cell culture incubator and split the next day as necessary. Three days post transfection the cells were employed for the respective experiments.

siRNA transfection mixture

96  $\mu$ L serum-free RPMI

+ 4  $\mu$ L siRNA (20  $\mu$ M stock)

mix

+ 6  $\mu$ L Hiperfect

incubate at RT for 15-20 min, apply on cells

### II.6.8.2 Transfection in 96 well format

96 well format transfections for large scale experiments were either performed automatically with the help of a pipetting robot or manually for smaller amounts of plates. Optimized transfection protocols using Hiperfect as transfection reagent were employed.

#### II.6.8.2.1 Automatic transfection

One day before transfection cells were seeded with a density of  $2.5 \times 10^3$  cells/well using the automatic 8-channel pipette (Biohit, Rosbach v. d. Höhe). A Qiagen pipetting robot (Biorobot 8000) was used for automatic

transfection of 96 well plates under semi-sterile working conditions. The respective program that controlled the pipetting steps of the robot was written and functionally tested by the RNAi group of Nikolaus Machuy and further adjusted to fulfil the specific needs. With the program “Doppelter 2.1.1 für Salmonellen”, the transfection of two cell plates with two different transfection plates per run was achieved. Prior to every run, the transfection reagent was prepared freshly (Hiperfect 1:20 in RPMI medium without FCS), pipette tips as well as the cell culture media were refilled and fresh aliquots of control siRNAs (Allstars, PLK and Rab7A; 1:100 in RPMI without FCS) were used. Cells were incubated at 37°C with 5% CO<sub>2</sub> in a humidified cell culture incubator. 24 h post transfection the medium was replaced by fresh, pre-warmed (37°C) RPMI full medium and the cells were incubated for two more days to allow gene knock down.

### II.6.8.2.2 Manual transfection

Cells were seeded as described above and the transfection complexes were mixed in sterile deep-well plates (Cole-Parmer, Vernon Hills, IL, USA) according to the table below using a manual 12 channel pipette, an automatic 12 channel pipette and an automatic 8 channel pipette (Biohit, Rosbach v. d. Höhe).

Table II.9: Manual transfection protocol

component	volume per well [μL]
RPMI Ø FCS	30
Hiperfect (1:40 in RPMI Ø FCS)	30
siRNA (1:100 in RPMI Ø FCS)	15
mix	
incubate at RT for 10 min	
RPMI full medium	150
aspirate 90 μL medium from the cells	
add 20 μL RPMI full medium to the cells	
add 75 μL of transfection complex/well	

Following transfection, cells were incubated and treated as described above (see II.6.7.2.1).

### II.6.9 Construction of stable shRNA transduced cell lines

The gene silencing mediated by siRNA molecules is a transient one. In order to achieve a permanent gene knock down, lentiviral encoded small hairpin (sh) RNA expression vectors were constructed and these were integrated into the target cell's genome. This ensures a constitutive expression of shRNA molecules and thereby a permanent gene knock down. By using a GFP reporter gene on the lentiviral plasmid, the transfection efficiency could be determined. Respective shRNA sequences (designed with the help of the RNAi designer from Invitrogen, Karlsruhe: <https://rnaidesigner.invitrogen.com/rnaiexpress>) were cloned into the vector pLVTHM and virus particles were produced by transfecting 293T cells with 20 μg of vector in combination with the packaging vectors psPAX2 (15 μg) and pMD2G (6 μg) using calcium phosphate transfection (DNA in 0.5 M CaCl<sub>2</sub> added 1:1 to 2xHBS; DNA-calciumphosphate precipitates are then added to the cells). 48 h post transfection, the filtered virus particles in the supernatant were transferred to HeLa cells with the help of polybrene (final concentration 1 mg/mL). The next day, the medium was replaced by fresh medium and five days later the knock down efficiency was tested by immunoblotting.

Table II.10: Sequences of shRNA constructs used in this study

shRNA	target gene	sequence	strain collection Nº of HeLa cell line	remarks
Luciferase	firefly luciferase	AACTTACGCTGAGTACTTCGA	HeLa05 Luci	neutral control
MKK7.1	mitogen-activated protein kinase 7	GCATTGAGATTGACCAGAAGC	HeLa05 OR01	
PLA2.1	phospholipase A2, group IVA	GGAGATTACGTTAATGGATGC	HeLa05 OR02	

## II.7 Molecular biological methods

### II.7.1 Preparation of plasmid DNA

Plasmid DNA was used for transformation of bacteria or as template for cloning experiments. For isolation of plasmid DNA from bacteria a mini or midi prep kit from Qiagen (Hilden) was used according to the manufacturer's instructions. The DNA concentration was measured spectrometrically using a Nanodrop ND-1000 device (peqlab, Erlangen).

### II.7.2 Polymerase chain reaction (PCR)

PCR was utilized for 1) the amplification of specific DNA fragments with explicit 5' and 3' restriction sites for cloning and 2) for amplification of DNA fragments for analytical purposes (e.g. colony PCR).

In table II.10 the composition of the reaction mixture as well as the standard protocol for PCR is depicted. For larger PCR approaches a master mix was prepared and distributed to the PCR reaction tubes (ABgene, Hamburg). 100-500 ng of purified DNA was used routinely, for colony PCR, some bacterial material was resuspended in 100  $\mu$ L ASC-H<sub>2</sub>O and 1  $\mu$ L of this mixture was employed for PCR. All reactions were performed in a GeneAmp thermocycler (Applied Biosystems, Carlsbad, CA, USA). Pfx50 DNA polymerase (Invitrogen, Karlsruhe) and "in-house" Taq DNA polymerase were applied for cloning PCR applications and simple analytical purposes, respectively. The PCR products were further analyzed by gel electrophoresis (see II.7.3).

Table II.11: PCR reaction mixture and PCR protocol

standard reaction mixture (30 $\mu$ L)		standard PCR protocol	
component	volume [ $\mu$ L]	condition	time
10 x reaction buffer	3	1. 95°C	5 min
dNTP's (10 mM each)	0.6	2. 95°C	30 sec
5' primer	0.6	3. 55°C	30-60 sec
3' primer	0.6	4. 68°C or 72°C	dependent on fragment size
DNA template	different	5. repeat steps 2-4	
		20-30 times	
100 mM MgCl <sub>2</sub> (if not part of reaction buffer)	0.9	6. 68°C or 72°C	5 min
enzyme	1		
H <sub>2</sub> O	ad 30 $\mu$ L		

### II.7.3 Quantitative Real Time-PCR (RT-PCR)

RT-PCR was used to quantify the amount of specific mRNA populations, e.g. after siRNA or shRNA mediated knock down experiments. For this, total RNA was isolated using the RNeasy RNA purification kit (Qiagen, Hilden). The reverse transcription of mRNA and the subsequent RT-PCR were performed in a ABI Prism 7900 HT system (Applied Biosystems, Carlsbad, CA, USA) using the QuantiTect SYBR Green Kit (Qiagen, Hilden).

### II.7.4 Gel electrophoresis

For the preparative analysis of DNA fragments or the excision of specific DNA fragments after restriction reactions, gel electrophoresis was performed. Here, DNA fragments are separated inside an agarose gel according to their migration speed along an electrical field.

Separation and detection of DNA fragments was performed in gels with 0.4-1.2 % [w/v] of agarose in 0.5x TBE and 1  $\mu$ g/mL ethidiumbromide. The samples were mixed with DNA loading buffer, loaded into the pockets of the gel and separated using 80-140 V for the aspired time. To visualize the DNA, the gel was inspected with a Gene Genius device (Syngene, Cambridge, UK) detecting the fluorescence of the DNA-intercalating dye ethidiumbromide. Fragment sizes were calculated by employing DNA standards (DNA ladder 1kb or 500 bp,

Fermentas, St. Leon-Rot). For excision of fragments from a gel a sharp, clean scalpel was used and the DNA was eluted from the agarose using a gel extraction kit (Qiagen, Hilden).

### **II.7.5 Endonuclease reaction**

In order to open plasmid DNA, to cut out DNA fragments from plasmids or to prepare PCR products for ligation reactions different restriction enzymes (all from NEB, Ipswich, MA, USA) were used. DNA was purified before restriction enzyme reactions using a PCR purification kit (Qiagen, Hilden) and multiple restriction reactions were performed sequentially with purification steps. If appropriate, BSA (NEB, Ipswich, MA, USA) was added to the digestion reaction. All experiments were performed in PCR tubes for two hours in a 37 °C incubator and the reaction products were purified again or separated with gel electrophoresis.

### **II.7.6 Filling of DNA overhangs**

To fill up DNA overhangs produced by enzymatic restriction T4 DNA polymerase (NEB, Ipswich, MA, USA) according to the manufacturer's advice was used. The reaction was incubated in a waterbath at 30°C for 60 min. The enzyme was heat-inactivated at 65°C for 10 min and the DNA was purified using a PCR purification kit (Qiagen, Hilden).

### **II.7.7 Dephosphorylation of DNA**

For dephosphorylation of DNA, Antarctic Phosphatase (NEB, Ipswich, MA, USA) was added to the purified DNA according to the manufacturer's advice and incubated at 37°C for 60 min. The enzyme was heat-inactivated at 65 °C for 10 min and purified using a PCR purification kit (Qiagen, Hilden).

### **II.7.8 Ligation**

Ligations of DNA fragments were carried out with the help of the Rapid DNA Ligation Kit (Roche, Hague Road, IN, USA). For each mixture 10 µL of pre-aliquoted ligation buffer containing ATP was used. A molecular ratio fragment:plasmid of 3:1 was employed and the ligation reaction was incubated for 15-30 min at RT, transferred on ice and then purified using the PCR purification kit (Qiagen, Hilden).

## **II.8 Biochemical methods**

### **II.8.1 Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE)**

Protein samples were separated according to their migration speed using the SDS PAGE. Samples were resuspended in 1x Laemmli buffer and boiled at 95 °C for 10 min for denaturation of proteins. Acrylamide concentrations from 10-15% were used and the samples were first loaded on a stacking gel before separation over a running gel to ensure similar running conditions. Voltages applied were 60 V and 140 V for stacking and running gel, respectively. A pre-stained protein marker (Fermentas, St. Leon-Rot) was loaded on every gel to inspect SDS PAGE progression and to estimate the size of the desired protein band.

### **II.8.2. Immunoblotting**

To detect specific antigens in a protein sample, the SDS PAGE separated proteins were blotted onto a Polyscreen PVDF membrane (Perkin-Elmer, Waltham, MA, USA). This was done using the semi-dry method and

a semi-dry blotting chamber (Biometra, Göttingen) with 1 mA of current per cm<sup>2</sup> of membrane for 60 min. The membrane was activated prior to use with 100% methanol and washed once in transfer buffer. After protein transfer the membrane was washed once with 1x TBS-T and blocked with 5% dry milk powder in 1x TBS-T at RT for 60 min followed by washing three times for 5 min with 1x TBS-T. In order to visualize specific protein bands, the membrane was incubated with the respective primary antibody, in an antibody specific dilution in 3% BSA/TBS-T, at 4 °C overnight with shaking. The membrane was washed 60 min with TBS-T and then the secondary antibody, coupled to HRP, was added 1:2000-3000 in 5% milk powder/ 1xTBS-T for 60 min at RT. The membrane was washed thoroughly and the antibody signals were detected by applying HRP substrate solution (GE HealthCare, Little Chalfont, UK) to the membrane and exposition to X-ray films (GE Healthcare, Little Chalfont, UK). For sequential detection of different proteins on the same membrane, the PVDF membrane was stripped in stripping buffer (50 °C, 20 min), washed once with isopropanol and thoroughly with distilled H<sub>2</sub>O. Subsequently, the membrane was blocked again and treated as described above.

### II.8.3 Immunoprecipitation (IP)

For the identification of protein-protein complexes immunoprecipitation was performed. Cells were seeded in 10 cm dishes (Corning, Lowell, MA, USA) to gain approx. 70 % confluency and the respective experiment was conducted. Afterwards, the dishes were put on ice and all subsequent steps were performed on ice and with pre-cooled (4°C) centrifuges. Cells were washed once with cold PBS and then 2 mL of cold PBS + PhosStop (Roche) (broad-range phosphatase inhibitor cocktail; one pellet in 10 mL) was added to the dish. Cells were gently scraped with a rubber policeman and the cell suspension was transferred to 2 mL Eppendorf tubes. The cells were pelleted at 1800 rpm, 4°C for 5 min and the supernatant was discarded. Cells were resuspended in 500 µL RIPA buffer + PhosStop (one pellet in 10 mL), incubated for 5 min on ice and then passaged ten times through a pre-cooled 0,25 mm needle to break up the cells. From this suspension 40 µL was removed and mixed with 40 µL 2x Lämmli buffer to yield the input control. The remaining lysate was centrifuged at 10,000 rpm for 10 min to pellet cell debris and the supernatant was transferred to new 1,5 mL Eppendorf tubes. The lysate was pre-incubated with 20 µL Dynabeads Protein G beads (Invitrogen, Karlsruhe; washed two times with PBS before use) for 30 min on a rotator in the cold room and then the antibody for pull-down was added 1:50. The lysates were incubated on a rotator overnight at 4°C. For recovery of protein complexes 100 µL Dynabeads Protein G beads were added and the lysates were incubated on a rotator at 4°C for 2 h. The samples were then washed two times with cold RIPA buffer by using the Dynal MPC -E concentrator (Invitrogen, Karlsruhe) for pelleting the beads. Afterwards the samples were washed two times with PBS and then 40 µL 2x Lämmli buffer was added and the samples were heated at 95°C for 10 min. The supernatant was transferred to new tubes and the beads were resuspended in 30 µL 2x Lämmli buffer and heated again and the supernatant was added to the previous one. Samples were stored at -20°C until SDS-PAGE and Immunoblotting was performed.

In order to avoid masking of proteins with an approximate molecular weight of around 50 kDa by the predominant denatured heavy chains of the IP antibody, a light-chain specific antibody was used for the immunoblots. A second, HRP-coupled antibody was then employed to detect the light-chain specific antibody.

## II.9 Microscopical methods

### II.9.1 Immunofluorescence staining

Immunofluorescence staining for confocal microscopy was performed in 24 well format on 12 mm acetone-washed, autoclaved coverslips. Cells were seeded with the desired density and treated as appropriate (e.g. infected with Salmonella Typhimurium).

The cells were fixed by adding 2% paraformaldehyde/PBS and incubating at 37°C for 10 min and then washed three times with PBS. For intracellular staining the cells were permeabilized with triton X-100 (0.2 % [v/v] in PBS at RT for 15 min). Following permeabilization the cells were washed extensively with PBS (RT) and treated as described in table II.12. All staining steps were performed at RT. The incubation with primary or secondary antibody was performed in a humidified chamber to prevent drying of the samples.

Table II.12: Immunofluorescence staining procedure

staining step	component	time
---------------	-----------	------

blocking	1% [w/v] BSA/PBS	30 min
primary antibody	antibody 1:50-1:200 in 0.1% BSA/PBS	60 min
washing	five times with PBS	
blocking	1% [w/v] BSA/PBS	15 min
secondary antibody	1:300 in 0.1% BSA/PBS	45 min
washing	five times with PBS	
washing	once with ddH <sub>2</sub> O	

The coverslips were mounted on glass-slides with mowiol and subjected to microscopic analysis.

## II.9.2 Confocal microscopy

A Leica TCS SP-1 (Wetzlar) was employed for confocal microscopy analysis. The samples were first inspected manually with the 63x objective, then images were acquired using the software Leica LCS. Images were further processed with the software Adobe Photoshop, e.g. to overlay different fluorescence channels.

## II.10 Fluorescence activated cell sorting (FACS), Flow Cytometry

During flow cytometric measurements a continuous stream of sample fluid, hydro-dynamically focused by a sheath fluid, passes a laser. Particles inside the sample scatter the laser light in a characteristic manner. Additionally, fluorescent compounds within the particle (such as fluorescent dyes) are excited and emit light of a specific wavelength. Both the scattered light and the emitted light are picked up by detectors, eventually are amplified for dim fluorescence, and thereby the measured particle can be analyzed multiparametrically (see supplementary figure S.4). This gives information about several physical and chemical properties on a single cell level. Historically, flow cytometry was used to phenotypically characterize eukaryotic cells, mainly human blood cells, but it is now also established for the measurement of bacteria.

For all flow cytometry experiments a FACS Calibur (BD, BD, Franklin Lakes, NJ, USA), equipped with a HTS loader device (BD, BD, Franklin Lakes, NJ, USA) for high-throughput applications was employed. The software controlled needle unit of the HTS supply is able to remove a specific sample volume from 96 well or 384 well plates and to apply it to the FACS device for parametric analysis. The software CellQuest Pro V5.2.1 or Plate Manager V1.0.1 (both: BD, BD, Franklin Lakes, NJ, USA) was used for single tube experiments or 96 well plate measurements, respectively. Before conducting 96 well plate experiments single tube measurements were performed to produce the required template and setting files.

### II.10.1 Single tube experiments

Samples (e.g. infected cells) were prepared as described elsewhere and then processed for flow cytometry. Cells were trypsinized, resuspended in PBS and fixed with 2% [w/v] PFA, bacterial solutions were fixed 1:1,000 – 1:10,000 in 2% [w/v] PFA and measured directly. It was observed that cells that were FACS-measured directly in the fixative solution displayed differing auto-fluorescence when compared to non-fixed cells. Additionally, the fluorescence of infected cells could not be analyzed adequately, most likely because the PFA altered the properties of the respective fluorescent proteins. Therefore, the fixative had to be removed to obtain proper FACS results which was carried out by transferring the cell samples to 1.5 mL Eppendorf tubes and pelleting them in an Eppendorf tabletop centrifuge at 520 x g at RT for 4 min. The supernatant was discarded and the cell pellet was resuspended in 400 µL PBS, transferred to FACS tubes and subjected to FACS analysis.

### II.10.2 High-throughput experiments

For 96 well plate FACS analysis the samples were prepared as described elsewhere. Prior to flow cytometry measurements, the cells were trypsinized inside the wells with 30 µL/well trypsin (RT) and incubated at 37°C

for 5 min until cells detached. The cells were resuspended with 70  $\mu$ L PBS (RT) and fixed with 2% [w/v] PFA (RT) at 37°C for 10 min. To remove the fixative the plates were centrifuged in a Heraeus multifuge 3 S-R (DJB Labcare, Newport Pagnell, UK) centrifuge at 1200 rpm and RT for 5 min to sediment cells and the supernatant was aspirated carefully from the wells. The cells were resuspended in 100  $\mu$ L/ well PBS and analyzed by FACS. Before high-throughput FACS acquisition, the system was primed 2-3 times.

### II.10.3 General FACS settings and data analysis

The fluorescence channels FL-1 and FL-3 were used to detect GFP or mCherry fluorescence, respectively. Both fluorescence signals were compensated against all other channels by performing single fluorescence experiments. Mammalian cells or bacteria were identified according to their light scattering properties using a forward scatter (FSC) and side scatter (SSC) dot plot. Autofluorescence of eukaryotic cells in the GFP channel was calculated by analysing non-infected cells and was used to define the population of infected cells. During 96 well plate measurements 40  $\mu$ L of each well was analysed to allow well-to-well comparison of cell concentrations. The raw data was further analysed with the software FlowJo 7.2.1 (Treestar, Ashland, OR, USA) or FCS Express (DeNovo software, Los Angeles, CA, USA) for high-throughput data and single tube experiment data, respectively. Processed high-throughput data was applied to prefabricated Excel forms for initial statistical analysis.

### II.11 Statistical analysis and bioinformatics

The FACS high-throughput raw data was analyzed with regard to the parameters described in table II.13 using the software FlowJo 7.2.1 (Treestar, Ashland, OR, USA). The data was applied to Excel analysis, the analytical parameter were normalized to the Allstars mean values and the mean inhibition of test siRNAs was calculated in relation to the control siRNAs Allstars (neutral) and Rab7A (inhibitory) using the following equation:

$$\frac{\text{Mean GFP value of Allstars controls} - \text{GFP value of test sample}}{\text{Mean GFP value of Allstars control} - \text{Mean GFP value of Rab7A\_2 controls}}$$

The toxic control siRNA PLK was used to inspect the knock down efficiency.

Table II.13: FACS parameters used for statistical analysis

analytical parameter	derived from FACS data
number of cells	number of cells in cell gate (FSC/SSC)
percentage of infected cells	ratio of eGFP-positive cells (FL-1)
eGFP fluorescence of infected cells	median eGFP fluorescence of eGFP-positive cells (FL-1)
percentage of mCherry positive cells	ratio of mCherry-positive cells (FL-3)
mCherry fluorescence of infected cells	median mCherry fluorescence of mCherry-positive cells (FL-3)

Further analysis involved the calculation of mean and standard deviation values from different experiments and the verification of statistical significance using Student's two-tailed t-test.

In general, only siRNAs that fulfilled the following criteria were regarded as possible "hits":

- 1.) non-toxic (cell count  $\geq 0.4$ )
- 2.) impact on GFP fluorescence (mean inhibition  $\geq 0.5$  for inhibitory and  $\leq -0.5$  for activating siRNAs)
- 3.) statistical significance (p-value  $\leq 0.05$ )

## III Results

### III.1 Assay development

The interaction between a pathogen and its host cell is a fascinating and highly complex subject that is intensively studied in many different fields of scientific research. A plethora of pathogen-host models is investigated with the aim to unravel important molecular pathways that underlie the elaborate interactions of pathogens and their host cells. Host signaling pathways that are activated in response to the infection or manipulated by the pathogen just like the virulence factors involved in pathogenesis are of strong interest to basic research. Transferring the increasing knowledge of these interactions to the applied sciences might allow developing new strategies to combat infections and control infectious diseases. With the advent of the RNA interference technique to specifically knock down the expression of eukaryotic genes, it became possible to examine the importance of certain host cell proteins for the establishment of a successful infection on a large scale. Recently, several RNAi based screens have been performed with diverse infection models of intracellular pathogens: *Listeria* (Agaisse *et al.*, 2005), *Chlamydia* (Derre *et al.*, 2007, Elwell *et al.*, 2008) or *Plasmodium* (Prudencio *et al.*, 2008). Without exception, all of these screens were conducted using microscopy as the principal read-out technique.

In this work, a FACS based assay was developed to evaluate the impact of RNAi mediated host cell gene knock down on intracellular growth of *Salmonella* Typhimurium. A *Salmonella* strain was constructed carrying two reporter plasmids which made it possible to monitor bacterial replication and metabolic fitness in one experimental run. Each reporter plasmid was responsible for the expression of a different fluorescent protein that could be detected and distinguished using FACS. This reporter strain satisfied the need and the wish to generate data of high content to cover as many parameters of the infection process as possible. After the construction and validation of the reporter strain, described in III.1.1 and III.1.2, respectively, the high-throughput FACS assay was set up and different conditions (e.g. cell seeding or infection parameters) were tested to ascertain the optimal experimental design (see III.1.3). Pre-screening experiments were performed to test the functionality of the assay and its applicability for large scale experiments (see III.1.4 and III.1.5) before the actual screening of large siRNA libraries was accomplished (see III.2).

#### III.1.1 Construction of a *Salmonella* Typhimurium reporter strain

Two reporter plasmids were constructed and electroporated into the *Salmonella* Typhimurium wildtype strain 12023 to obtain the sensor strain for monitoring both intracellular bacterial replication and fitness (see figure III.1). This sensor strain was thought to enable the acquisition of very detailed data regarding the impact of host cell gene knock down on the infection process of *Salmonella* in one experimental run.

The plasmid pOR25 drives the constitutive expression of the green fluorescent protein (GFP) from the bacterial promoter  $\phi$ prpsM. GFP can be easily excited with the FACS laser line of 488 nm and is detected at 530 nm (fluorescence channel FL-1). The vector pACYC177 (Chang *et al.*, 1978) was used as the back bone for cloning pOR25. It harbours two antibiotic resistance genes: *bla* for ampicillin resistance and *kan* for kanamycin resistance. Since it was intended to apply a second reporter construct also carrying an ampicillin resistance gene,

the *bla* gene of pACYC177 had to be interrupted to ensure an equal propagation of both plasmids inside *Salmonella* under selective conditions. For this, the plasmid pACYC177 was

**Figure III.1: Schematic diagrams of the cloning strategies for pOR25 and pOR26.**

The cloning schemes for the construction of the reporter plasmids pOR25 and pOR26 are shown in [A] and [B], respectively. See text for details.

digested with the enzyme BsaHI to cut the vector 5' of the *bla* gene and inside the gene. Subsequently, the plasmid was re-ligated, electroporated into *E. coli* DH5 $\alpha$ , and tested on ampicillin and kanamycin agar plates. No growth on ampicillin plates could be observed indicating that the disruption of the *bla* gene was successful. In order to clone the  $\phi$ rpsM-GFP fusion into the modified pACYC177 vector (pACYC177 'ampR'), the respective fragment was digested from the plasmid pFPV25.1 (Valdivia *et al.*, 1996) using the enzymes XbaI and SphI and was treated with T4 DNA polymerase to produce blunt ends. The pACYC177 'ampR' vector was digested with BamHI, was T4 DNA polymerase-treated and then dephosphorylated. The rpsM-GFP fragment was ligated into the modified vector pACYC177 to gain the reporter plasmid pOR25 (see figure III.1).

The second reporter plasmid, pOR26, was constructed using the vector pBAD18 (Guzman *et al.*, 1995) which constitutes an arabinose inducible expression system. It has been widely used in heterologous protein expression (Ghigo *et al.*, 2000, Low *et al.*, 2006) and also for the controlled expression of GFP, luciferase, and lysis gene E in a *Salmonella* infection model (Loessner *et al.*, 2007). A DNA fragment of mCherry, flanked by a 5' XbaI and a 3' HindIII restriction site was synthesized from the plasmid pRSET mCherry (Shaner *et al.*, 2004) by PCR with primers FP\_new-F and FP\_new-R and digested with the enzymes XbaI and HindIII to produce cohesive DNA ends. The vector pBAD18 was digested with XbaI/HindIII, dephosphorylated and the PCR fragment was ligated to produce the plasmid pOR26 (see figure III.1).

Both plasmids were propagated in *E. coli* DH5 $\alpha$  and sequenced with primers flanking the ligated insert. The DNA sequencing was performed by SMB DNA Sequencing Service Martin Meixner (Berlin) and showed a correct DNA sequence for both constructs.

The plasmids were electroporated sequentially into the *Salmonella* Typhimurium 12023 wild type strain and the resulting strain 12023 pOR25/26 was grown on ampicillin/kanamycin selective agar plates to ensure propagation of both plasmids.

### III.1.2 Validation of the reporter strain

#### III.1.2.1 The viability of the reporter strain is not altered

In order to test the viability of the double-transformed strain 12023 pOR25/26, the growth in LB medium was compared to the growth of the wild type 12023 strain. Both strains were grown overnight at 37°C, 200 rpm. They were diluted 1:100 in fresh medium and the OD<sub>600</sub> was measured at different time points. Figure III.2 depicts the growth curves of both the wild type strain and the strain 12023 pOR25/26. It becomes obvious that there was no significant difference between both strains. This indicates that the viability of the reporter strain was not impaired by the propagation of the two plasmids (see figure III.1).

**Figure III.2: The reporter strain is not impaired in growth.**

The *Salmonella* Typhimurium 12023 wildtype strain and the reporter strain 12023 pOR25/26 were cultivated overnight in LB medium. At the indicated time points after subcultivation, samples were taken and the OD<sub>600</sub> was measured to control bacterial growth. The plot shows the data of three independent experiments as means with standard deviations for the wildtype strain (open triangles) and the reporter strain (filled triangles).

### III.1.2.2 Expression of both fluorescent proteins can be detected and discerned by FACS

#### III.1.2.2.1 FACS analysis of the reporter strain in-vitro

The functionality of the plasmids pOR25 and pOR26 was first tested *in-vitro*. The strain 12023 pOR25/26 was grown in defined PCN culture medium overnight with glucose and then subcultured 1:50 in fresh PCN medium with glucose for 2h. Since the availability of glucose completely represses the arabinose expression system (Guzman *et al.*, 1995), the bacteria were pelleted, washed two times with ddH<sub>2</sub>O and resuspended in PCN medium without glucose, supplemented with 0.2 % [w/v] arabinose to induce the expression of mCherry.

**Figure III.3: The expression of both fluorescent proteins can be monitored using FACS.**

In order to test the functionality of the reporter strain the fluorescence of GFP and mCherry was monitored using flow cytometry. Bacterial cultures of 12023 pOR25/26 were grown in PCN medium with glucose overnight, subcultured 1:50 in fresh medium for 2 hours and then washed with dH<sub>2</sub>O. Pellets were resuspended in PCN medium without glucose, supplemented with 0.2 % [w/v] L-arabinose and grown for the indicated time. Samples were fixed with 2% PFA and then measured with a FACS Calibur. The spectral overlap of GFP and mCherry was compensated during measurements.

[A] Non-induced (grey) and induced (black) cultures were analyzed for their fluorescent characteristics, showing clearly distinguishable populations. [B] The mCherry fluorescence intensity increases with induction time, indicated by the shift of the histograms. Time points were 0 (grey filled), 15 (dashed), 30 (dotted), 60 (dash-dotted) and 120 (black filled) minutes, respectively. [C] The triplicate data of one representative experiment with means and standard deviations for GFP fluorescence (open triangles) and OD<sub>600</sub> (filled triangles) is shown.

Samples were taken at different time points and analyzed by FACS as described in II.10.1. Figure III.3.A illustrates the respective dot plot for GFP and mCherry fluorescence with spectral compensation. A clearly distinguishable population showing GFP as well as mCherry fluorescence originated 2 h post induction whereas the non-induced bacterial culture only exhibited GFP fluorescence. In figure III.3.B, the mCherry fluorescence at different time points after arabinose addition is depicted. It becomes obvious that a significant shift in fluorescence intensity occurred 2 h post induction that could be easily discerned from the background fluorescence (figure III.3.B; grey shaded curve).

Figure III.3.C displays the GFP fluorescence as well as the OD<sub>600</sub> of the bacteria over time after subcultivation in glucose-free PCN medium. Characteristic curves showing a growth phase dependent GFP expression driven by the ribosomal protein promoter  $\phi_{rpsM}$  can be seen.

#### III.1.2.2.2 FACS analysis of the reporter strain in cell culture infections

In order to test the reporter plasmids *in-vivo* and, moreover, to find the adequate cell line for the performance of the high-throughput screen, several human tissue culture lines were infected with the reporter strain for FACS analysis. 14 h p.i. the samples were treated with induction medium for 2 h, were processed as described in II.10.1 and were analyzed for GFP and mCherry fluorescence. Samples were taken at 2 h p.i. and 16 h p.i. for the analysis of the initial bacterial invasion and the long-term infection process, respectively.

Figure III.4 reveals that the infection efficiency strongly varied among the different cell lines investigated. Using the dot plot view (figure III.4.A) it is possible to discern and quantify different cell populations: 1.) non-infected cells in quadrant three (Q3), 2.) infected cells displaying only GFP-expressing bacteria (Q4) and 3.) infected cells showing both GFP and mCherry fluorescence (Q2). The visual inspection of the dot plots further displays remarkable differences in the infection efficiency of the different human cell lines with *Salmonella* under the conditions used. For instance, GFP intensity as well as the infection rate was much lower in infected HT-29 cells than in infected HeLa cells.

The quantification of important infection parameters within the different cell lines is depicted in figure III.4.B. Samples were analyzed 16 hours p.i. for replication (upper and middle panel) and 2 hours p.i. for invasion (lower panel). The analysis implied the rate of cells showing the correspondent fluorescence signal and the intensity of GFP or mCherry fluorescence. Distinct differences between the cell lines could be observed with regard to the initial bacterial invasion rate, the replication efficiency in these cells or the ability of the bacteria to express the mCherry protein. The invasion rate was comparable among all cell lines tested except HepG2 cells which showed a significantly lower bacterial invasion (see figure III.4.B, lower panel). The amount of GFP fluorescence was equal in HeLa and Hec1b cells but lower in the other cell lines used, indicating that fewer bacteria per cell had entered. 16 h p.i. the percentage of infected cells was in the same range as 2 h p.i. for HeLa, Hec1b, HepG2, and HEp-2 cells but had dropped dramatically for HT-29 cells (see figure III.4.B, upper panel). Additionally, the bacteria in HT-29 and HepG2 cells only showed a weak mCherry induction after overnight infection (see figure III.4.B, middle panel), indicating that the bacterial metabolic activity was weak under these conditions. For HEp-2 cells two distinct populations of infected cells could be observed (see figure III.4.A), one showing a GFP/mCherry fluorescence pattern similar to HeLa cells and one that displayed lower mCherry expression levels which resulted in relatively lower values for mCherry intensity in

the quantification. This suggested that HEp-2 displays a heterogeneous cell line with regard to *Salmonella* infection and was therefore not considered to be used within the screen. Thus, based on the results gained from infection experiments with different human cell lines, the HeLa cell line proved to be an adequate tool to investigate intracellular replication and fitness of *Salmonella* Typhimurium and it was therefore used for all subsequent experiments if not stated otherwise.

**Figure III.4: FACS analysis of different cell lines infected with the reporter strain.**

Using the reporter strain in a FACS assay, fundamental infection parameters can be quantified showing significant differences between the cell lines tested. Human cell lines (1: HeLa, 2: Hec1b, 3: HepG2, 4: HEp-2 and 5: HT-29) were seeded in 24 well plates, infected with a MOI of 200 and processed for FACS analysis as described in II.10. Dot plots were generated and then further analyzed for quantification using FlowJo 7.2.1.

[A] Two-parametric dot plots of infected human cell lines with the log GFP fluorescence intensity on the x-axis and the log mCherry fluorescence intensity on the y-axis. [B] Quantification of different infection parameters as indicated. Upper and middle panel: 16 hours p.i. Lower panel: 2 hours p.i.

### III.1.2.2.3 Microscopic analysis of the reporter strain in cell culture infection

For microscopic analysis of the reporter strain, HeLa cells were seeded on coverslips, infected with the reporter strain and treated with induction medium to induce mCherry expression or were left untreated.

Figure III.5 depicts the confocal microscopic analysis for sequentially acquired GFP and mCherry fluorescence as well as the image overlay. In the non-induced sample only GFP

fluorescence is detectable, whereas in arabinose stimulated cells most of the bacteria show GFP as well as mCherry fluorescence, as reflected by the overlay image. This is a further proof that the reporter constructs are working reliably and that *Salmonella* bacteria inside their host cell can be induced to express the mCherry protein by the external addition of arabinose.

**Figure III.5: Intracellular replicating *Salmonella* can be induced to express mCherry.**

HeLa cells were seeded on coverslips and infected with the reporter strain as described in II. 14 h p.i., samples were either treated with induction medium for 2 hours or left untreated and were processed for confocal analysis. Images are shown for the GFP fluorescence (left images), the mCherry fluorescence (middle images), and the overlay of both channels (right images). In the upper panel and the lower panel representative intracellular bacteria are shown for non-treated and treated cells, respectively. Scale bar = 2  $\mu$ m

### III.1.3 Development of a high-throughput FACS application

After having evaluated the sensor strain intensively *in-vitro* and *in-vivo*, the assay was transferred to a large scale application to perform high-throughput screening experiments in a 96 well plate format. As mentioned above, it was chosen to use the human epithelial cell line HeLa for the experiments for the following reasons: 1. the cell line is the predominantly used epithelial cell infection model in *Salmonella* research, 2. it gave the best results with respect to the infection parameters measured in the FACS analysis (see III.1.2.2.2 and figure III.4) and 3. there had already been good expertise in successfully transfecting HeLa cells with siRNAs inside the department. For the establishment of the high-throughput assay several details had to be evaluated, such as the overall robustness of the FACS measurements performed with the HTS supply and the proper infection conditions.

### III.1.3.1 Stability of measurements

The FACS Calibur HTS supply is equipped with a mobile needle that removes a specified sample volume from a 96 well or 384 well plate and injects it into the flow system which transports the sample to the flow chamber for parametric analysis (see figure S.4 in the supplements).

Since the processing of one 96 well plate with this supply takes about 30 min to 1 h (in normal working mode and dependent on sample volume and sample speed), it was necessary to assure a stable measurement of sample over the time and for the whole plate. To test the technical variation of measurements over time, HeLa cells fixed with 2 % [w/v] PFA were pipetted into a 96 well plate at a density of  $4 \times 10^4$  cells/well and were measured with the help of the HTS supply and the conditions specified below. Only the inner 60 wells were acquired since in the planned RNAi experiments the outer wells would be omitted due to already observed irregular growth behaviours of cells in the outer wells. During the whole time of acquisition, the amount of cells remained stable as in all 60 wells an equal number of cells could be detected (figure III.6). Thus, the high-throughput FACS analysis ensures a high technical reproducibility under the conditions used.

**Figure III.6: The HTS FACS acquisition is stable over time.**

In order to evaluate the variability of the FACS HTS measurement over time, PFA-fixed cells were pipetted at equal density into the wells of a 96 well plate. Afterwards the inner 60 wells of the plate were measured with identical conditions: 40  $\mu$ L/well at a speed of 2  $\mu$ L/sec. Each bar represents a well and the wells are depicted in the order of measurement. The number of acquired cells is presented on the y-axis.

### III.1.3.2 Infection conditions and assay accuracy

#### III.1.3.2.1 Determination of appropriate infection conditions

After having secured that the general technical variation of the measurements was in a range that could be tolerated, the adequate infection conditions had to be determined. In order to evaluate the proper infection dose to avoid cell toxicity, a multiplicity of infection (MOI) titration experiment was performed. The impact of different MOIs on cell survival and infection parameters in a 96 well plate format HeLa cell infection, analyzed by high-throughput FACS acquisition, is shown in figure III.7. The amount of measured cells normalized to non-infected cells exhibited a MOI dependent decrease, indicating

a tremendous cell toxicity of 84% for HeLa cells infected with a MOI of 200 compared to a relatively low toxicity caused by MOIs of 10 and 20 (figure III.7.A).

The infection efficiency (i.e. the percentage of GFP-positive cells that were detected) was also MOI dependent displaying an infection rate of about 80 % for MOI 200 and about 40 % for cells infected with a MOI of 10 (figure III.7.B). For the median GFP fluorescence intensity of infected cells no MOI dependence could be observed. For all MOI conditions employed, a similar value of GFP fluorescence intensity per cell was measured (figure III.7.C).

These results suggested the use of MOI 20 for the infection of HeLa cells with *Salmonella* Typhimurium as the cell toxicity was negligible and at the same time the infection parameters proved to be adequate.

**Figure III.7: MOI titration for evaluating the appropriate infection conditions.**

HeLa cells were seeded in 96 well format, infected and processed for FACS analysis 16 h p.i. Ten wells for each MOI were analyzed. The data of one representative experiment with means and standard deviations is shown. [A] Number of detected cell particles, normalized to non-infected cells (MOI 0). [B] Percentage of infected cells (i.e. infection rate). [C] Median GFP fluorescence of infected cells.

### III.1.3.2.2 Accuracy of the FACS assay

The toxicity of certain siRNAs might lead to variable cell numbers in the wells. The impact of lower or higher cell numbers on the infection was tested in a 96 well format experiment by seeding different cell numbers and infecting at MOI of 20 (see figure III.8). The respective amount of bacteria to reach MOI 20 was adjusted with respect to the samples with  $1 \times 10^4$

**Figure III.8: *Salmonella* reporter strain infections run stable with varying cell densities.**

To test the impact of differing cell numbers on the infection parameters, HeLa cells were seeded in 96 well format at a density of 1:  $4 \times 10^4$ , 2:  $2 \times 10^4$ , 3:  $1 \times 10^4$ , 4:  $5 \times 10^3$ , 5:  $2.5 \times 10^3$  and 6:  $1.25 \times 10^3$ . Cells were infected the next day with a MOI of 20 as adjusted for the cell density of samples with  $1 \times 10^4$  cells seeded. 16 h p.i. cells were processed for FACS analysis and ten wells for each condition were measured. The data of one experiment with triplicates, normalized to  $1 \times 10^4$  cells seeded (white bar), with means and standard deviations is shown for [A] number of cells detected, [B] invasion rate and [C] median GFP fluorescence of infected cells. P-values \* $<0.05$  and \*\* $<0.01$  with  $1 \times 10^4$  cells as reference.

cells seeded. The FACS analysis showed that the detected cell numbers within a constant volume of 40  $\mu$ L decreased with diminishing seeding quantities (figure III.8.A). Concerning the invasion rate of the bacteria, a significant difference to the reference value (white bar in figure III.8) could only be detected for extreme high or low cell numbers ( $4 \times 10^4$  and  $1.25 \times 10^3$ ), whereas in the range from  $2.5 \times 10^3$  to  $2 \times 10^4$  cells, the invasion rate was

**Figure III.9: FACS assay shows high accuracy of measurements over a wide range of particle numbers.**

Different volumes of infected cells were loaded from each well and analyzed by flow cytometry. The volume in  $\mu$ L that was analyzed is displayed on the x-axis. The y-axis shows GFP fluorescence [A] or invasion rate [B] on the left and the number of detected cells on the right.

comparable (figure III.8.B). No significant difference could be observed with respect to the GFP fluorescence intensity (figure III.8.C). Thus, the infection with the reporter strain runs similar over a certain range of host cell densities providing certain stability against eventual differences in cell numbers due to toxic siRNAs. Next, it was of interest to figure out whether the detected cell number had an influence on the statistical robustness of measurements. In order to determine the range of cell numbers that gave comparable analysis data, an

accuracy assay experiment was performed. An equal number of HeLa cells was seeded into the wells of a 96 well plate, infected the next day as described (II.6.5) and the plate was processed for flow cytometry. For FACS acquisition, different volumes were taken out of different wells by the HTS supply and analyzed. The quantification of the FACS data is depicted in figure III.9. As expected, the number of detected cell particles increased with rising volumes measured. However, the values for the rate of infected cells and for the GFP fluorescence were comparable within the whole range of analyzed volumes. This shows that even with very low cell numbers, which might occur during the screen as a consequence of toxic siRNAs, a statistical robustness is assured using the FACS technique.

### III.1.4 Functionality test: small antibiotic screen

In order to demonstrate that inhibition of bacterial replication inside epithelial cells can be monitored with the bichromatic FACS assay, a small antibiotic screen in 96 well plate format

**Figure III.10: Small antibiotic screen as a functionality test.**

The applicability of the reporter strain FACS assay was finally validated in 96 well format testing several antibiotics in different concentrations for their impact on bacterial replication and host cell toxicity. HeLa cells were infected with the reporter strain and 1 hour p.i. the medium was aspirated and 100  $\mu$ L/well RPMI full medium, supplemented with 20  $\mu$ g/mL gentamicin and the indicated concentration of drug was added for the rest of the infection. 14 hours p.i. the medium was aspirated, mCherry expression was induced and 2 hours later the samples were processed for FACS analysis. The plots show the number of cells detected (right y-axis and open squares) and median GFP fluorescence of infected cells (left y-axis and open triangles) one of experiment. Applied concentrations are displayed on the x-axis. Drugs used were: 1 chloramphenicol, 2 irgasan, 3 streptomycin, 4 erythromycin, 5 tetracyclin, 6 cefixim, 7 rifampicin, 8 trimethoprim, 9 brefeldin A, 10 H-89 and 11 DMSO (as control). Concentration units are as follows:  $\mu$ g/mL (1-9),  $\mu$ M (10), % [v/v] (11).

was performed. Various antibiotics and chemical inhibitors were applied at different concentrations on cells infected with the reporter strain 1 hour post infection for the rest of the infection process and the plate was processed for FACS acquisition.

Figure III.10 shows the impact of different antibiotics on host cell survival and GFP fluorescence of the bacteria. For most of the inhibitors that were used in this small screen a decrease in GFP intensity was observed at higher concentrations. In the case of Irgasan, a phenol compound widely used as disinfectant and preservative, the cell toxicity was also very pronounced at the highest concentration of 100 µg/mL.

### III.1.5 Rab7A as the siRNA control for conducting the RNAi screens

After intensive functional evaluation of the bichromatic FACS assay, the set-up of the RNAi screen had to be further approached. Most importantly, it was necessary to find and establish siRNAs that could operate as control siRNAs throughout the whole screen. The siRNA controls are of great importance as they allow for monitoring the transfection efficiency itself and as they serve as markers for the statistical analysis of the siRNAs to test. The following siRNA controls had to be concerned: 1. a neutral control to assess the overall impact of the siRNA transfection process on the host cell as well as on the infection, 2. a toxic siRNA that kills the host cells in a reliable way to directly control the transfection efficiency, and 3. a siRNA that leads to a host cell gene knock down which stably inhibits the bacterial infection process leading to a decrease of fluorescence.

A commercially available scrambled siRNA sequence named Allstars (Qiagen, Hilden) served as the neutral control. This sequence should not lead to a specific gene knock down and, moreover, was designed by the company in a way to cause only minimal off-target effects. A siRNA against the host cell protein PLK1, the polo-like kinase 1 which is involved in mitosis, was used as a toxic control due to already existing profound experiences with this sequence in our laboratory. Upon transfection with this sequence, the majority of cells was killed within three days.

In order to find a control siRNA which would reliably inhibit *Salmonella* replication, the respective literature was screened. Some reports describe a role for Rab7 in the infection process of *Salmonella*. For instance, Meresse et al. (1999) showed that Rab7 is involved in the biogenesis of the *Salmonella* containing vacuole (SCV) by mediating the acquisition of lysosomal glycoproteins (lgp) which are evident on mature vacuoles. In another publication a role of Rab7 for the formation of *Salmonella* induced filaments (Sifs), which is essential for the replication, was reported (Brumell et al., 2001b). Thus, Rab7 seems to play an important role in the accurate maturation of the SCV and thereby ensures the successful bacterial replication inside the vacuole. Based on these observations it was decided to test the impact of Rab7 gene knock down on *Salmonella* intracellular growth by flow cytometry (III.1.5.1), by confocal microscopy (III.1.5.2), and with a gentamicin protection assay (III.1.5.3) to evaluate its employment as the inhibitory siRNA control. For this, Dharmacon Rab7A smart pool siRNAs were purchased and initially tested with the FACS assay.

#### III.1.5.1 FACS based evaluation of Rab7A knock down on infection

To test the impact of the Dharmacon smart pool mediated Rab7A gene knock down on *Salmonella* intracellular growth, Hela cells were transfected with the respective siRNA in 96 well format, infected three days post transfection, and analyzed by FACS.

As illustrated in figure III.11.A, the mean GFP fluorescence of infected Rab7A knock down cells was reduced to about 50% compared to Allstars control treated cells. This indicates a strong replication defect in the absence of Rab7A. The dot plot analysis of Rab7A treated cells showed a significant shift of the infected cell population compared to Allstars treated cells (figure III.11.C). Additionally, the mCherry signal dropped into the range of the non-infected background intensity, implicating that the bacteria responded only very weakly to the arabinose trigger. This indicates that the Rab7A knock down caused to a strong inhibition of bacterial replication and metabolic activity and, thus, exhibits an excellent control to monitor the inhibition of *Salmonella* infection during the screening conductance.

**Figure III.11: Impact of Dharmacon smart pool mediated Rab7A knock down on *Salmonella* infection of HeLa cells.**

HeLa cells were seeded in 96 well format and transfected with Allstars control siRNA or the Dharmacon Rab7A smart pool siRNAs. Three days later cells were infected with MOI 20 and processed for FACS analysis. Six wells were measured for each condition and the data from one representative experiment with means and standard deviations is shown. [A] Median GFP fluorescence of infected cells normalized to Allstars. [B] Mean number of cells detected, normalized to Allstars. [C] FACS two-parametric dot plots for Allstars (upper plot) and Rab7A (lower plot) treated samples.

However, it has to be noted that the transfection with the smart pool had significant cytotoxic effects as the normalized cell number decreased to about 50% (figure III.11.B). It was therefore resolved to test all four siRNAs that are combined in the smart pool separately. Although the knock down was comparably efficient for all sequences and the smart pool on protein level (figure III.12.C; lower band in Rab7A panel), their influence on cell survival differed significantly (figure III.12.A). Whereas the siRNA sequences 1 and 3 as well as the pool had a negative impact on the number of detected cell particles (16, 18, and 27%, respectively, compared to Allstars), the inhibition of bacterial replication (i.e. the GFP expression) was comparable for all Rab7A siRNAs tested ( $77.9 \pm 15.6$  for sequence 1,  $65.4 \pm$

7.4 for sequence 2,  $61 \pm 14.9$  for sequence 3,  $78.4 \pm 5.8$  for sequence 4 and  $62.4 \pm 10.2$  for the pool; Mean  $\pm$  SD, n=6). Based on these results it was decided to use the Dharmacon Rab7A siRNA sequence 2 because it had a good knock down efficiency, showed no host cell toxicity, and was effective in inhibiting bacterial replication. The FACS analysis of Allstars and Rab7A\_2 treated cells is depicted in figure III.12.D (Allstars: left; Rab7A\_2: right) demonstrating a strong inhibition of both GFP and mCherry fluorescence after Rab7A\_2 transfection.

**Figure III.12: Individual Rab7A siRNAs differ in their biological properties.**

The siRNAs sequences that were part of the Dharmacon Rab7A smart pool were purchased separately and tested for their knock down efficiency and their influence on host cell survival and *Salmonella* infection. HeLa cells were seeded in 96 well format and transfected with the individual siRNAs and the pool. Three days later the cells were infected with MOI 20 and processed for FACS. The mean cell number [A] and median GFP fluorescence [B] of one representative experiment with means and standard deviations is depicted (n=6). [C] Western blot analysis of cell samples three days post transfection with the respective siRNA. [D] Representative two-parametric dot plots for Allstars (left) and Rab7A\_2 (right) treated cells.

A: Allstars M: mock N°: different Rab7A sequences 1-4: Rab7A siRNA pool

### III.1.5.2 Microscopic evaluation of Rab7A knock down on infection

In order to further phenotypically characterize the impact of Rab7A knock down on the bacterial infection process, Rab7A\_2 transfected cells were analyzed using a confocal microscope. HeLa cells were seeded and infected as described in II.6.5 and processed for confocal microscopy analysis. The GFP and the mCherry fluorescence channel were acquired sequentially and the editing of the confocal images was performed with Adobe Photoshop. As can be seen in figure III.13, the knock down of Rab7A caused a dramatic inhibition of the bacterial infection process. No mCherry expression could be detected in the representative infected cell and the GFP-positive vesicle-like structures differed significantly from the usual appearance of the *Salmonella* containing vacuole as shown in the Allstars control images,

namely, significantly less bacteria and a more scattered distribution of the small vesicles. These observations suggest that the absence of Rab7A in the host cell provoked incomplete fusion events between different bacteria-containing phagosomal structures. This would be in accordance to the publications cited above.

**Figure III.13: Confocal analysis of Rab7A knock down cells displays inhibition of bacterial replication and metabolic activity.**

HeLa cells were seeded on coverslips in 24 well format and transfected either with the Allstars siRNA or the Rab7A siRNA. Three days post transfection the cells were infected and treated with induction medium for two hours. The fluorescence channels for GFP and mCherry were acquired sequentially to avoid spectral overlap and images were edited using Adobe Photoshop. Representative images of Allstars (upper panel) and Rab7A (lower panel) treated cells and the fluorescence channels for GFP (left) and mCherry (middle) as well as the overlay of both channels (right) are depicted. Scale bar = 10  $\mu$ m.

### III.1.5.3 Quantification of bacterial replication

The quantification of bacterial replication in Rab7A\_2 treated cells compared to Allstars transfected control cells was carried out with the help of the gentamicin protection assay (see II.6.6). Allstars or Rab7A\_2 transfected cells were infected and 2 h p.i. and 16 h p.i. samples were lysed, serial diluted and plated on selective agar plates for counting colony forming units (cfu). The replication rate was calculated by the ratio of cfu at 16 h p.i. and cfu at 2 h p.i.

Figure III.14 presents the bacterial replication rates for Allstars or Rab7A\_2 treated cells. It could be observed that the replication rate of *Salmonella* inside Rab7A\_2 transfected cells is significantly lower than in Allstars control cells ( $30 \pm 7.9$  for Allstars and  $12.8 \pm 2.4$  for Rab7A\_2; Mean  $\pm$  SD, n=3). This finding again allocates that the knock down of Rab7A inhibited bacterial replication inside HeLa cells.

In summary, the data gained with the FACS assay, confocal microscopy, and gentamicin protection assay demonstrate that the depletion of Rab7A has a significant adverse biological effect on the *Salmonella* infection process. The stability of FACS measurements made after Rab7A knock down using the sequence Rab7A\_2 additionally legitimates the employment of this siRNA as the inhibitory control for the screening experiments.

**Figure III.14: Gentamicin protection assay demonstrates a significant bacterial replication defect in Rab7A knock down cells.**

In order to calculate the bacterial replication rate, a gentamicin protection assay was performed. Transfected HeLa cells were infected and at 2 hours p.i. and 16 h p.i. infected cells were lysed with triton, the lysates were serial diluted and plated on selective agar plates to count bacterial colonies. The replication rate was calculated by the ratio of recovered bacteria at 16 h p.i. and 2 h p.i. The data shows a representative experiment with means and standard deviations (n=3) for Allstars treated and Rab7A\_2 treated cells. P-value <0.05.

## III.2 Large scale RNAi screening and statistical analysis

### III.2.1 Primary screen

Two siRNA libraries were employed for large scale RNAi screening experiments using the high-throughput bi-chromatic FACS assay, namely, 1. the SOS library, containing varied siRNA sequences used in our laboratory, and 2. the validated kinase library (SKV). The composition and the properties of the libraries are summarized in table III.1.

Both libraries were already distributed into the 48 inner wells of 96 well plates, solved in RPMI medium without FCS with a concentration of 200 nM and stored at -80°C. These plates are from now on called the transfection plates. Each plate could be used for two transfection experiments using the pipetting robot. The automatic transfections were carried out as described in II.6.8.2.1 using the plate scheme depicted in figure S.1.

The SOS library was screened first with testing every transfection plate at least three times, followed by the SKV screen. The acquired raw data from the siRNA libraries was further processed with the respective software (see II.11) and analyzed statistically.

Table III.1: siRNA library composition and properties

library	Nº of genes	Nº of siRNAs per gene	Nº of plates	composition	source
SOS	480	1	10	non-related	in-house
SKV	588	2	26	kinase genes	Qiagen

Initially, it was important to validate the quality and robustness of the screening data. In a first analysis step, the mean inhibition values for Rab7A of all plates and runs were calculated and plotted to control the stability of the down-regulating control siRNA throughout the whole screening procedure (see figure III.15). As holds true for both libraries, the GFP fluorescence in the Rab7A samples normalized to Allstars was comparable within the whole amount of plates and runs with a total mean of about 0.68 and 0.65 for the SKV and the SOS library, respectively. Based on these results, the inhibition data of the siRNAs to test that was calculated on the basis of the Allstars and Rab7A values could be considered as reliable and was therefore analyzed further.

**Figure III.15: Statistical robustness of the Rab7A siRNA control.**

The reliability and quality of the screening data was validated in a first step by analyzing the stability of the Rab7A inhibitory control for all plates screened. The median values of all Rab7A replicates for each plate were used to calculate the respective decrease in GFP intensity normalized to Allstars. The box-plots show the median (line in box), the upper and lower quartile (box), the 2.5% percentile (lower whisker) and the 97.5% percentile (upper whisker). Plates are shown in their order for the SKV library [A] and the SOS library [B]. The means and standard deviations for the medians of all plates are shown in [C].

To obtain an overview of the distribution of critical screening parameters, the entire data sets for the SKV and the SOS library were further analyzed for mean plate inhibition and cell toxicity as well as inhibition on the single siRNA level. The respective diagrams are shown in

figure III.16. In order to guarantee an unbiased plate allocation of the transfection plates, the mean inhibition of the collectivity of siRNAs in one plate should be in the range of zero. This, indeed, was the case for both library plates as indicated by the box plot characteristics

**Figure III.16: Analysis of whole screening data.**

The entire screening data set that was acquired for the SKV library (left side) and the SOS library (right side) was statistically validated. [A] Mean inhibition of all test siRNAs for each plate reveals no phenotypic bias (mean values approximately zero) in neither the SKV or the SOS library produced by the allocation of the plates. Plates are shown in their order. [B] Overall cell toxicity of every sample siRNA sequence, normalized to Allstars, in quantitative order. [C] Mean inhibition values for every siRNA sequence in quantitative order.

(figure III.16.A). Thus, the quality of the plates with regard to the unbiased distribution of the test siRNAs was proven. The cell number of each siRNA sequence, normalized to Allstars, revealed a difference in cell toxicity between the SKV and the SOS library (figure III.16.B). Whereas the overall toxicity of siRNAs of the SKV library was relatively moderate, a higher number of siRNA sequences of the SOS library showed significant cell toxicity. This is also demonstrated by the quantification diagram (figure III.17.A). Additionally, the mean inhibition values of the individual siRNAs of the SOS library showed a slight bias to a down-regulating phenotype (figure III.16.C). This becomes also obvious from the quantification shown in figure III.17.B. The observed bias is probably founded in the more pronounced toxicity of the SOS siRNAs leading to inadequate infection conditions.

The relatively high number of toxic siRNAs in both libraries made it necessary to carefully check the tested siRNAs for their impact on cell number before evaluating their importance for the bacterial infection process, namely the GFP and mCherry fluorescence. Therefore, a three step selection procedure was performed as described in II.11. First, the normalized cell counts were examined and all siRNAs that showed a significant cell loss (cell counts < 0.4) were excluded from further analysis. Next, the mean inhibition was queried to specify siRNAs as up-regulating ( $\leq -0.5$ ) or down-regulating ( $\geq 0.5$ ). As the last criterion, the

**Figure III.17: Higher toxicity and a biased phenotype in the SOS library.**

The entire screening data from the SKV and the SOS library was quantified with regard to the cell toxicity [A] and the impact on *Salmonella* growth [B]. > 0.5: relevant inhibition of *Salmonella* replication; < -0.5: relevant up-regulation of *Salmonella* replication. white bars: SKV library grey bars: SOS library

statistical significance for the mean inhibition with Allstars as reference was calculated using the Student's t-test and a value of < 0.05 was defined as implying significant differences. This procedure is allegorized in figure III.18 which shows "volcano plots" for the data from the SKV and the SOS library. In this two dimensional graphical analysis method the statistical significance of the inhibition values (p-value) was plotted against the values for the mean inhibition. Characteristic volcano shaped distribution patterns occurred and simplified the selection of promising siRNAs for further validation. Only siRNAs located in the shaded areas, i.e. siRNAs that fulfilled the criteria for significance (p-value < 0.05) and inhibition ( $\leq -0.5$  or  $\geq 0.5$ , see above), were considered as being relevant. They were finally evaluated with respect to their cell toxicity. A complete list with the toxicity and phenotypic results for all siRNA sequences from the SKV library can be found in the supplement (see table S.1). The solid analysis with regard to the criteria mentioned above gave a list of candidate genes that

**Figure III.18: Volcano plots of SKV and SOS data.**

The mean data of all siRNA sequences for mean inhibition (x-axis) and p-value (y-axis) was plotted as is shown for the SKV library [A] and the SOS library [B]. Samples that fulfill the criteria for mean inhibition and significance are located in the grey shaded areas. They were further analyzed by applying the cell count threshold to serve as validation candidates.

were considered as possible screening hits. Due to technical restrictions only a limited number of siRNAs could be integrated into the validation process with the main focus on SKV siRNA targets. The 48 chosen candidate genes of the SKV library with their mean inhibition and p values are listed in figure III.19 and in the supplementary table S.3. 20 of these showed a down-regulating phenotype, whereas 28 caused an upregulation of the infection. It has to be mentioned that for all of the candidate genes that were chosen for the subsequent validation only one out of two siRNAs from the SKV library showed the effect. Although, the library was validated for knock down efficiency, this result might have resulted from inadequate knock down rates.

**Figure III.19: Selected candidate genes of the primary SKV screen.**

After statistical analysis of the data from the primary SKV screen, 48 candidate genes were chosen for validation. Their impact on *Salmonella* growth is illustrated on the left, the mean values of at least three independent experiments with SD for each candidate. The statistical significance of the mean inhibition of all candidates with Allstars as reference is shown on the right.

This first selection of siRNA sequences that caused a decrease in GFP fluorescence was further analyzed implying the second fluorescence read-out. For this, the ratio of the mCherry fluorescence and the GFP fluorescence was calculated to test for shifts in the fluorescence intensity (figure III.20.A). The Allstars treated sample was used as a neutral control and as the reference for calculating the statistical significance. Cells depleted of Rab7A displayed a significantly lower ratio, normalized to Allstars ( $69 \pm 5$ , mean and SD,  $n = 4$ ,  $p$ -value  $< 0.001$ ). This was also the case for MKNK2 and EIF2AK3 ( $84 \pm 10$  and  $72 \pm 19$ ,  $p$ -values  $< 0.05$ ), MAP2K7, AKT2, MAP3K7, CDC2L1 and MAP3K7IP1 ( $75 \pm 10$ ,  $81 \pm 8$ ,  $64 \pm 17$ ,  $79 \pm 10$  and  $63 \pm 15$ ,  $p$ -values  $< 0.01$ ) and BEGAIN ( $66 \pm 11$ ,  $p$ -value  $< 0.001$ ).

The difference in the mCherry/GFP ratio gave a first indication that the bacterial metabolic activity could have been impaired after siRNA mediated knock down of the respective genes

since the ratio normally shows a linear course and a lower value would be a sign of differentially distributed cell populations (see figure III.4; dot plots with different cell lines and figure III.12; dot plot of Rab7A depleted cells). To further evaluate this, the quadrants two and four containing GFP/mCherry and GFP-only cells (harboring presumably metabolic inactive bacteria), respectively, were determined and the ratio of the according percentages was calculated. In figure III.20, the diagrams for the ratio normalized to Allstars (figure II.20.B) as well as the respective dot plots (figure II.20.C) are depicted. Rab7A knock down

**Figure III.20: Bichromatic FACS read-out allows further phenotypically validation of primary hits.**

All primary hits that showed a down-regulation of infection were further evaluated using the different fluorescence properties of both fluorescence reporters. [A] Ratio of mCherry and GFP fluorescence of infected cells with the respective siRNAs. The value of Allstars treated cells was taken as reference for the calculation of the statistical significance. Values below the Allstars reference indicate proportionally lower mCherry fluorescence. The data shown are means from at least three independent experiments with SD. P-values are <0.05, <0.01, and <0.001, respectively. [B] The ratio of particles detected in quadrants two (GFP and mCherry) and four (GFP only) for targets that were identified as being significant in [A], normalized to Allstars. [C] Respective dot plots for the targets from [B] with GFP and mCherry fluorescence on the x-axis and y-axis, respectively.

cells displayed a much lower ratio, indicating only small numbers of GFP/mCherry positive cells which was in accordance to the microscopic analysis and bacterial quantification described in III.1.5.2 and III.1.5.3, respectively. A similar phenotype could be seen for MAP3K7IP1 and EIF2AK3, whereas the other samples showed no significant differences to the Allstars control value. The mathematically derived rating could be underlined by the

corresponding dot plots. For Rab7A, MAP3K7IP1 and EIF2AK3 a strong shift of the infected population could be observed (see figure III.20.C)

### III.2.2 Validation of screening results

The primary screen resulted in 48 possible hits for the SKV library. In order to increase the reliability of the acquired phenotypes the primary hits had to be further validated. This was achieved by ordering siRNA oligonucleotides targeting the genes of interest with sequences different from those already examined within the screen. Due to technical reasons, the validation was focused on the kinase library (SKV). All genes that were part of the validation process are listed in table S.2 (supplement). For each gene, four individual siRNA sequences were ordered from Qiagen according to their availability. They were delivered in 96 well plates and resuspended to gain the transfection plates for the SKV validation. The transfection and infection experiments were performed manually as described in II.6.8.2.2 and the statistical analysis was carried out similarly to the one described before.

Table III.2 shows the results of the validation experiments for those siRNAs that showed a phenotype in the validation experiments. The mean inhibition values of the primary screen are included, to allow direct comparison of the results for the different siRNAs. For the validation data the strongest inhibition value is given along with the number of siRNA sequences that yielded the respective phenotype.

Table III.2: Validated kinases constituting possible candidates for functional characterization

siRNA target	function	Gene ID	% inhibition		phenotype	
			<u>screen</u>	<u>validation</u>	<u>screen</u>	<u>validation</u>
CSNK1D	casein kinase	1453	0.72	- 0.52 (1/4)	down	up
EIF2AK3	translation initiation factor kinase 3	9451	0.83	- 1.25 (2/4)	down	up
ACVR2	activin receptor	92	- 0.71	- 0.52 (2/4)	up	up
CERK	ceramide kinase	64781	- 1.0	- 0.3 (1/4)	up	(up)
AK1	adenylate kinase		- 0.81	- 0.57 (2/4)	up	up
SNF1LK2	salt-inducible kinase 2	23235	- 1.13	- 0.67 (2/4)	up	up
MAPK3	mitogen-activated kinase 3	5595	- 0.77	- 0.47 (2/4)	up	(up)
PGK1	phosphoglycerate kinase 1	5230	- 0.96	- 0.65 (4/4)	up	up
MAP2K7	mitogen-activated kinase kinase 7	5609	0.94	0.71 (3/4)	down	down
MAP3K7IP1	TAK1-binding protein 1	10454	0.73	- 0.73 (2/4)	down	up
CSNK1G3	casein kinase	1456	- 1.0	0.89 (2/4)	up	down
NEK7	NIMA-related kinase 7	140609	- 0.72	- 0.45 (2/4)	up	(up)
MERTK	c-mer proto-oncogene	10461	- 1.13	- 0.72 (2/4)	up	up
MKNK2	MAPK interacting kinase 2	2872	1.10	- 0.65 (3/4)	down	up
MAP3K7	TGF activated kinase	6885	0.83	- 0.41 (3/4)	down	(up)

### III.3 Functional characterization to reveal the role of the mitogen-activated protein kinase kinase 7 (MKK7) during *Salmonella* infection of epithelial cells

After the validation of the primary screening data with additional independent siRNA sequences, a set of host cell genes that play a role during *Salmonella* growth in HeLa cells was compiled (see table III.2). A major challenge was then to decide on the factor that would be integrated into follow-up experiments to derive functional data. First, the comparison between primary screening data and validation results was taken into account, especially the phenotype of *Salmonella* growth (up/down). Interestingly, for a lot of targets oppositional phenotypes were observed (see table III.2) which characterized these targets as less interesting for further studies. Additionally, the robustness of the validation, i.e. the number of siRNA sequences showing the same trend of phenotype, was considered. Finally, it was surveyed whether helpful scientific publications regarding a host cell factor and *Salmonella* infection had already been published. Therefore, the considerations of possible follow-up targets led to the decision to functionally characterize the mitogen-activated protein kinase kinase 7 (MAP2K7 or MKK7) during *Salmonella* infection for the following reasons:

1. The knock down of MKK7 resulted in the inhibition of *Salmonella* growth both in the primary screen and the validation (same phenotype),
2. Within the validation, three out of four siRNA sequences showed the same phenotypic trend, and
3. MAP kinases are known to play a role during *Salmonella* invasion and replication.k

Several MAPKs have been reported to be activated by *Salmonella*, mainly in the context of pro-inflammatory host responses (see Introduction part for details). Therefore, they play a significant role in infections with this pathogen. MKK7 is involved in mediating the response to pro-inflammatory cytokines such as TNF $\alpha$  and other environmental stress stimuli, predominantly by activating the effector MAPK c-jun N-terminal kinase (JNK)(Tournier *et al.*, 1997). One important pathway of cellular stress is the release of the second messenger arachidonic acid (AA) from cell membrane phospholipids, catalyzed by the ubiquitously expressed enzyme cytosolic phospholipase A2 alpha (cPLA2) (Chakraborti, 2003) which can also be phosphorylated by MAPKs (Lin *et al.*, 1993, Borsch-Haubold *et al.*, 1998, Hefner *et al.*, 2000). AA then stimulates the synthesis of prostaglandins. Interestingly, Galan and colleagues demonstrated that an inhibitor of cPLA2 is able to decrease the invasion rate of *Salmonella* Typhimurium into cultured epithelial cells, arguing that cPLA2 activity is involved in this process (Pace *et al.*, 1993). They also observed an increase in intracellular calcium, which stimulates the localization of cPLA2 from the cytosol to membranes and thereby leads to its activation. In the same report phosphorylation of the MAPK Erk was shown upon *Salmonella* attachment and invasion resembling signaling through the epidermal growth factor receptor (EGFR). Taken together one could speculate that cPLA2 is activated through the MAPK pathway and active cPLA2 is necessary for *Salmonella* invasion and probably also subsequent replication which could be demonstrated for the intracellular bacterium *Chlamydia trachomatis* (Su *et al.*, 2004). In this context, the knock down of MKK7 might lead to a decrease of cPLA2 activity. This could cause an inhibition of bacterial invasion and/or replication. Therefore the role of MKK7 and cPLA2 in *Salmonella* infection was further characterized.

### III.3.1 MKK7 knock down reduces *Salmonella* intracellular growth

MKK7 was identified within the kinome screen as being important for *Salmonella* intracellular growth. Infected HeLa cells showed less GFP fluorescence after MKK7 knock down compared to Allstars treated cells. A representative FACS histogram is depicted in figure III.21.A. The grey shaded curve and the black line resembles Allstars treated cells and MKK7 treated cells, respectively. A shift in GFP fluorescence could be observed for MKK7 treated cells resulting in approximately 30 % reduction of GFP intensity (figure III.21.B). In order to evaluate the FACS derived inhibitory phenotype for MKK7 knock down, gentamicin protection assays were performed as described in II.6.6. This allowed quantification of intracellular bacterial replication in Mock, Allstars and MKK7 treated HeLa cells. As a confirmation for the FACS results, the gentamicin protection assay using siRNA-treated HeLa

**Figure III.21: MKK7 knock down inhibits *Salmonella* intracellular growth.**

The impact of MKK7 kd on *Salmonella* intracellular growth was evaluated with the FACS assay and with gentamicin protection assays. [A] A representative FACS histogram showing the GFP fluorescence of Allstars transfected cells (grey shaded curve) and MKK7 transfected cells (black line). [B] Quantification of the GFP fluorescence from infected cells after Allstars or MKK7 transfection as mean with SD from triplicates. [C] Gentamicin assay of Allstars treated cells (white) or MKK7 treated cells (grey) showing the replication rate normalized to Allstars as the mean with SD from three individual experiments. [D] Gentamicin assay of Luciferase (white) or MKK7 (grey) shRNA transfected cells showing the replication rate normalized to Allstars as mean with SD from two individual experiments.

cells revealed a significant decrease of replicating bacteria in MKK7-depleted host cells (figure III.21.C). This was further validated with a shRNA-mediated MKK7 stable knock down HeLa cell line (figure III.21.D).

Taken together, these experimental data verified that the depletion of MKK7 inhibits *Salmonella* intracellular replication.

### III.3.2 cPLA2 is activated in *Salmonella* infected cells

MAPK have been reported to be involved in the activation of cPLA2, a molecule that was described to be involved in *Salmonella* invasion. In order to find out whether the knock down of the MAPK MKK7 had an influence on cPLA2 activation directly or indirectly and thereby caused an inhibition of bacterial infection, initially, a possible activation of cPLA2 during *Salmonella* infection was investigated.

**Figure III.22: cPLA2 is phosphorylated and activated upon *Salmonella* infection.**

[A] Infected or non-infected HeLa cells were prepared for immunoblotting at different time-points. Cell lysates were probed for Ser505 phosphorylated cPLA2 (p-cPLA2), total cPLA2, bacterial Hsp60 and actin as loading control. [upper part] Immunoblots showing the respective samples. [lower part] Quantification of the relative amount of phosphorylated cPLA2 in the respective samples, normalized to the non-infected control at 0 min (black bar). PMA: phorbol-12-myristate-13-acetate; CAM: chloramphenicol [B] The enzymatic activity of cPLA2 was quantified in non-infected (white bar) and infected (grey bar) cells at the respective time-points using a specific fluorescent dye and FACS analysis.

HeLa cells were seeded in 24 well plate format and were either infected with a MOI of 50 or left uninfected. Uninfected cells were either left untreated or stimulated with 100 nM phorbol-12-myristate-13-acetate (PMA), a non-specific inducer of several pro-inflammatory pathways serving as a positive control. One infected sample was treated with 10 µg/mL chloramphenicol (CAM) 2 h p.i. to prevent bacterial replication. Cells were lysed with 1x Lämmli buffer at different time-points and the cell lysates were tested for cPLA2 phosphorylation by SDS-PAGE and immunoblotting using an antibody specific for

phosphorylated cPLA2. Additionally, bacterial Hsp60 was detected to monitor bacterial replication and total cPLA2 and actin detection were used to assess relative cPLA2 phosphorylation or equal sample loading, respectively. For quantification of the relative amount of phosphorylated cPLA2, immunoblots were processed with ImageJ (<http://rsbweb.nih.gov/ij/index.html>). First, all actin signals were normalized to the intensity of the non-infected sample from time-point zero. Then, total cPLA2 was normalized to this value and finally the intensity of phosphorylated cPLA2 was set into relation to total cPLA2. Additionally, cPLA2 enzymatic activity was monitored in non-infected and infected cells at different time-points using a specific substrate and resulting fluorescence was measured with a FACS Calibur.

Figure III.22.A reveals that cPLA2 became phosphorylated very early in infection. Already five minutes p.i. a significantly stronger band of expected size compared to the non-infected background level could be observed which could also be quantified using ImageJ (III.22.A, lower part). The phosphorylation of cPLA2 remained equal during the infection time tested with a slight decrease 20 hours p.i. (see quantification in figure III.22). The chloramphenicol-treated sample showed less phosphorylation which, nevertheless, was stronger than in the control sample. This observation was further verified with the quantification of cPLA2 enzymatic activity (figure III.22.B). Here, a higher activity was measured for infected cells 2 h p.i. compared to non-infected which was in comparison to the phosphorylation levels detected. This activity was less at 20 h p.i. but still higher than in control cells, indicating a sustained enzymatic activity of cPLA2 in infected cells. The demonstrated phosphorylation and induction of enzymatic activity by *Salmonella* Typhimurium might be a hint for the requirement of cPLA2 enzymatic activity for the efficient replication of the pathogen.

### III.3.3 cPLA2 is necessary for *Salmonella* intracellular replication

The infection time course revealed an activation of PLA2 during *Salmonella* infection (figure III.22), indicating that cPLA2 might be important for *Salmonella* growth in epithelial cells. To test this, the expression of cPLA2 was silenced using specific siRNAs (PLA2\_1 and PLA2\_2 as a

**Figure III.23: cPLA is necessary for *Salmonella* intracellular replication.**

The intracellular replication rate was quantified with the help of the gentamicin assay for siRNA-treated cells [A] or shRNA treated cells [B]. Intracellular replication was normalized to the controls Allstars [A] or Luciferase [B]. Mean data from two experiments with SD is shown. P-values: \*\*<0.01; \*\*\*<0.001.

pool) or by constructing a stable cPLA2 knock down cell line and gentamicin protection assays were performed as described in II.6.6. The results of these experiments are presented in figure III.23. It becomes obvious that the knock down of cPLA2 reduced the intracellular replication of bacteria to about sixty percent of the control level.

### III.3.4 MKK7 knock down provokes reduced cPLA2 protein levels

In contrast to the results described above, Galan and colleagues reported on the requirement of cPLA2 for the *Salmonella* invasion process (Pace *et al.*, 1993). In their study, the authors argued that MAPKs are likely to be involved in this process. However, the role of MKK7 in cPLA2 activation was not evaluated. To do so in this work, cPLA2 phosphorylation during infection in the absence of MKK7 was ascertained.

HeLa cells were seeded in 12 well plates and 24 hours later they were either mock transfected or transfected with Allstars siRNA or MKK7 siRNAs. Three days post transfection cells were infected with *Salmonella* Typhimurium 12023 wt with a MOI of 50. 2 h p.i. cells were lysed and tested for cPLA2 phosphorylation by SDS-PAGE and immunoblotting using a

**Figure III.24: MKK7 knock down provokes reduced cPLA2 protein levels.**

HeLa cells were either mock transfected or transfected with Allstars siRNA or a pool of two siRNAs targeting MKK7. Three days post transfection cells were infected and 2 h p.i. cells were lysed and subjected to SDS-PAGE and immunoblotting. [A] Immunoblot showing respective lysates analyzed for phospho-cPLA2 (first row), total cPLA2 (second row), MKK7 (third row), and actin as loading control (fourth row). [B] Quantification of the immunoblot displayed in [A]. Shown are the values for MKK7 (white bar), cPLA2 (light grey bar), and the ratio of phosphorylated to total cPLA2 (dark grey bar), normalized to mock transfected cells.

phosphorylation-specific antibody. Total cPLA2 and MKK7 levels were detected with respective antibodies and actin detection was used to assess equal sample loading. The knock down of MKK7 using a pool of two siRNAs was successful demonstrated by a significantly weaker band of expected size (see third row for MKK7 siRNA in figure III.24.A and white bar in III.24.B). In the MKK7 knock down sample also the levels of phosphorylated cPLA2 (first row) as well as total cPLA2 (second row) were considerably lower than in control transfected cells (Allstars and Mock), indicating that the knock down of MKK7 caused changes in the protein level of cPLA2 during infection. Although the total levels of cPLA2 were considerably lower in MKK7 depleted cells, the relative phosphorylation level of cPLA2 (i.e. ratio of phosphorylated to total cPLA2) was the same under all conditions applied (see

dark grey bar in III.24.B). Therefore, a MKK7 dependent control of cPLA2 levels seems likely which could account for the observed downregulation of *Salmonella* infection upon MKK7 knock down.

### III.3.5 MKK7 and cPLA2 do not form a stable protein complex

Both MKK7 and cPLA2 are involved in the intracellular replication of *Salmonella* in epithelial cells which was demonstrated by siRNA or shRNA mediated knock down experiments. Additionally, it was observed that upon MKK7 depletion the protein levels of cPLA2 decline which could explain the inhibitory phenotype of MKK7 knock down. Although to date, there are no reports on a physical interaction between MKK7 and cPLA2 it could be possible that MKK7 forms a complex with cPLA2, thereby stabilizing this protein. Similar observations have been reported for inhibitor of apoptosis protein (IAP) complexes (Rajalingam *et al.*, 2006).

**Figure III.25: MKK7 and cPLA2 do not form a stable complex.**

HeLa cells were seeded in 10 cm dishes and 24 h later treated for 2 h as follows: Ø, no treatment; P, 100 nM PMA; L, 10 ng/μL *E. coli* LPS; S, *Salmonella* Typhimurium 12023 wt (MOI 50). Samples were prepared for Co-IP as described in II.8.3 and proteins were detected using specific antibodies. [A] Input and IP samples from a Co-IP using a MKK7 antibody that were analyzed for cPLA2 (upper panel) and MKK7 (lower panel). [B] Input and IP samples from a Co-IP using a cPLA2 antibody that were analyzed for cPLA2 (upper panel) and MKK7 (lower panel).

In order to find out whether MKK7 and cPLA2 form a stable complex, co-immunoprecipitation (Co-IP) experiments were performed as described in II.8.3.  $2.4 \times 10^6$  HeLa cells were seeded in 10 cm dishes. The next day the cells were differentially treated as described in the legend of figure III.25 and 2 hours later they were processed for Co-IP using either an antibody against MKK7 or against cPLA2 for pull-down. Pre-clear lysates as input control and immunoprecipitated lysates were applied to SDS-PAGE and immunoblotting to detect MKK7 and cPLA2. In order to avoid masking of the MKK7 signal by the denatured heavy chain of the IP antibody, a light chain specific secondary antibody was used (see II.8.3). The Co-IP studies revealed that there is no direct interaction of the MAP kinase and PLA2 (figure III.25). Within all input samples (left part) distinct bands for cPLA2 and MKK7

could be observed. However, after pull down of MKK7 no cPLA2 signal was detected (figure III.25.A, upper panel in right part) and vice versa (figure III.25.B, lower panel in right part), indicating that under the conditions used cPLA2 could not be co-immunoprecipitated with MKK7. This suggests that MKK7 and cPLA2 do not form a stable complex.

### III.3.6 MKK7 regulates the expression of cPLA2

Given the fact that the Co-IP for MKK7 and cPLA was negative, a control of cPLA on protein level exerted by MKK7 seemed unlikely. In order to test whether MKK7 regulates the expression of cPLA2, HeLa cells were either transfected with Allstars control siRNA or with different siRNAs targeting MKK7 or cPLA2 and the relative cPLA2 mRNA amounts were detected by quantitative RT-PCR (figure III.26). Indeed, following MKK7 knockdown with two different siRNA sequences, the mRNA levels of cPLA2 also decreased significantly (figure III.26). This implicates that MKK7 is involved in the transcriptional regulation of cPLA2.

**Figure III.26: MKK7 regulates cPLA2 expression.**

HeLa cells were transfected with Allstars control siRNA or with different siRNA sequences targeting MKK7 and cPLA2. Three days post transfection cells were lysed and RNA was isolated. The relative cPLA2 mRNA amount was detected using RT-PCR.

### III.3.7 cPLA2 knock down leads to an increased formation of filiform Sifs

In order to further functionally characterize the impact of cPLA2 knock down on intracellular bacteria, HeLa cells were either transfected with Allstars or cPLA2 siRNAs, infected with *Salmonella* Typhimurium constantly expressing the mCherry protein and 16 h p.i. the samples were stained for the lysosomal marker protein LAMP-1. This lysosomal marker helps to visualize the structure and form of the *Salmonella* induced filaments (Sifs) which are an indication for the accommodation of *Salmonella* Typhimurium inside epithelial cells. Figure III.27.A displays exemplary confocal images of Allstars or cPLA2 transfected cells. Bacteria

**Figure III.27: Knock down of cPLA2 induces the formation of filiform Sifs.**

HeLa cells were treated either with Allstars or cPLA2 siRNAs and infected with *Salmonella* Typhimurium, constitutively expressing the mCherry protein (red colour in [A]). 16 h p.i. samples were stained for LAMP-1 (grey colour in [A]) and images were acquired using a confocal microscope. [A] Exemplary images of infected cells treated with Allstars (upper panel) or cPLA2 (lower panel) siRNAs. Thick, mature Sifs are indicated by arrows, filiform Sifs by arrowheads. Scale bar: 10  $\mu$ m. [B] Quantification of infected cells showing the filiform Sif structure. Data shown is from one experiment and at least twenty infected cells were analyzed.

are false colour stained in red and LAMP-1 is false colour stained in grey. Interestingly, it was observed that in a significant proportion of infected cPLA2 kd cells, Sifs appeared very thin and filamentous (see arrowheads in figure III.27.A) as compared to the more robust and

thick structure of Sifs in Allstars transfected cells (see arrows in figure III.27.A). The initial observation was quantified by counting at least twenty infected cells for both conditions. Stacks of three confocal planes were merged and the percentage of infected cells showing filiform Sifs was calculated (see figure III.27.B). In cPLA2 depleted cells, about 50 % of infected cells show filiform Sifs, compared to 16 % of infected cells in Allstars-treated samples. This indicates that cPLA2 plays a role in the formation of regular Sifs, probably by its enzymatic activity which enables the lipid modification of Sif membranes.

## IV Discussion

Intracellular pathogens rely on cellular functions of their host cells to establish a niche suitable for growth and replication. Key aspects of successfully concluding an infection are the invasion of the host cell, intracellular accommodation and replication, and subsequent release from infected cells to initiate a new infectious cycle. During all of these stages, components of the host cell machinery must be exploited to arrange conditions favourable for the pathogen. In this context it is conceivable that different pathogens use common host cell pathways but also distinct ones which reflect specific needs and evolutionary adaptations. The study of molecular pathways used by intracellular pathogens contains the capacity to gain a deeper insight into basic cellular processes of the host cell. *Salmonella* Typhimurium constitutes an ideal model organism to study bacterial interactions with host cells. It is a Gram negative facultative intracellular bacterium which induces its uptake into a variety of different eukaryotic cell types by the delivery of effector proteins via a type three secretion system (T3SS). It can be cultivated on solid agar plates as well as in liquid medium and it is readily accessible to genetic manipulations, making it comparatively easy to deploy under normal laboratory conditions. Since *Salmonella* are also very relevant pathogens for humans and livestock, research on the intracellular lifestyle of this organism shall contribute to further development of antimicrobial therapies. Intensive genetic studies on the bacterial side have identified a number of important virulence factors, which mostly became obvious using *Salmonella* Typhimurium mutants in cell culture or mouse infections. This led to a comparatively good knowledge of bacterial factors and their regulation that play a role in *Salmonella* interplay with host cells. On the other side, only a few host cell factors have been identified so far that are targeted by *Salmonella* to establish a successful infection. This was mainly due to the lack of techniques to routinely generate cell lines exhibiting a specific genetic deletion. Therefore, scientific research was mainly restricted to cells isolated from knock out mice or to overexpression of dominant-negative forms of proteins of interest. With the discovery of the RNAi pathway in eukaryotes, a powerful tool to study eukaryotic gene function emerged which also showed to be auxiliary in disclosing pathogen-host cell interactions on a molecular level. Despite drawbacks of the RNAi technique, the possibility to evaluate the impact of a specific host cell gene knock down on the course of infection will certainly contribute significantly to the understanding of the many ways pathogens have evolved to exploit host cell processes.

In this work, a technical system was set up to precisely monitor the intracellular growth of *Salmonella* Typhimurium inside eukaryotic host cells. This was achieved by using the green fluorescent protein (GFP) together with a derivative of the *Discosoma* sp. Red fluorescent protein (DsRed), named mCherry, as reporter genes for bacterial replication and metabolic activity. The principal readout system for this assay was flow cytometry but it also proofed to be applicable to microscopy. With this robust assay RNAi screens were performed employing two different siRNA libraries and the impact of host cell gene knock down on *Salmonella* intracellular growth was verified. The screening was followed by statistical analysis and intensive validation to distil host cell factors that are involved in *Salmonella* Typhimurium infection of the human epithelial cell line HeLa.

The *Salmonella* Typhimurium reporter strain was generated by constructing two plasmids that were introduced into the wild type strain 12023. The first plasmid, pOR25, expresses the GFP variant GFPmut3 (Cormack *et al.*, 1996) under a constitutively active promoter,

$\Phi$ rpsM. This reporter allows to monitor the bacterial replication both *in-vitro* and *in-vivo*. The FACS analysis of single bacteria *in-vitro* showed a characteristic GFP fluorescence intensity curve over time. This was set in correlation to the growth phase at the respective time-point (see figure III.3.C). Since the promoter  $\Phi$ rpsM drives the expression of a gene encoding a ribosomal protein which is especially necessary in rapidly dividing bacteria with high protein turnover, the GFP intensity of single bacteria increases when the bacteria are in the logarithmic growth phase. When entering the late-logarithmic and later the stationary phase, the activity of the *rpsM* promoter declines and the GFP intensity decreases due to dilution during cell divisions. However, this scenario can be seen only under ideal growth conditions, especially in a nutrient rich environment. The conditions of the nutrient poor *Salmonella* containing vacuole (SCV) inside the host cell do not allow a dilution of GFP molecules among dividing bacteria when the  $\Phi$ rpsM activity is reduced, resulting in less GFP intensity, since the replication rates *in-vitro* and *in-vivo* are not comparable. Rather, the relatively long half-life of the GFP molecule, which was estimated to be more than 24 h (Andersen *et al.*, 1998), leads to an accumulation of GFP inside the bacteria and therefore the GFP fluorescence intensity will increase in relation to the number of bacteria inside the vacuole (Thone *et al.*, 2007). This allows for monitoring intracellular bacterial replication using the GFP intensity as a general fluorescence reporter. Nevertheless, when not following the growth of intracellular bacteria in a time-course experiment but rather only determining one time-point, as during the performance of a high-throughput screen, the stability of the GFPmut3 molecule brings about the problem to distinguish between slowly replicating bacteria and those that are unable to replicate at a certain time-point of the infectious cycle. Both bacterial populations will probably display a comparable GFP intensity but with dramatically different underlying phenotypes. Thus, in order to query the vitality of intracellular bacteria shortly before performing the FACS analysis, an inducible reporter system was developed, the plasmid pOR26. Here, the fluorescent protein mCherry is expressed under the control of the promoter  $\Phi$ araBAD which is induced by arabinose (Guzman *et al.*, 1995). Since the bacteria have to be in a metabolic active state to react to the arabinose trigger, the mCherry fluorescence intensity can serve as an additional indicator for the impact of host cell gene depletion on the fitness of intracellular bacteria. In FACS and confocal microscopy experiments within this work, it could be demonstrated that the external addition of arabinose was able to stimulate intracellular *Salmonella* to express the mCherry protein (see figure III.4 and III.5). Interestingly, these experiments also showed that the compound arabinose was taken up into the SCV, indicating that a respective sugar transporter could be located at the SCV membrane. Additionally, because the presence of glucose totally represses the  $\Phi$ araBAD (Guzman *et al.*, 1995), the induction of mCherry expression from the plasmid pOR26 suggests that the SCV environment is avoid of glucose. In summary, the combination of two functionally distinct bacterial reporter systems in one *Salmonella* reporter strain made it possible to monitor both bacterial replication and metabolic activity in one experimental run. The applicability of the reporter strain could be demonstrated conclusively in HeLa cells that had been depleted of Rab7A by siRNA transfection. The GFP intensity of infected cells after Rab7A siRNA treatment was about 30 % lower than in Allstars treated control cells at 16 h p.i. (see figure III.12.B). This indicated a moderate replication inhibition upon Rab7A depletion. However, the induction of mCherry after arabinose addition nearly completely failed in Rab7A treated cells as can be seen in figure III.12.D, suggesting that the majority of intracellular bacteria resided in a metabolic inactive state, most likely because the Rab7A knock down had a significantly deleterious effect on *Salmonella* survival. Alternatively, it is possible that the transport of arabinose to

the SCV was inhibited in the absence of the small GTPase Rab7A which is a central regulator of endosomal vesicle trafficking. This possibility can be excluded when taking into account the results from the gentamicin protection assay (see figure III.14). The quantification of bacterial replication using this method further demonstrated that the intracellular replication of *Salmonella* Typhimurium is significantly inhibited upon Rab7A knock down. This phenotype could be persuasively verified using the bichromatic reporter strain 12023 pOR25/26, making it an adequate tool for the global RNAi analysis approach.

In order to perform high-throughput RNAi screenings the *Salmonella* reporter strain assay had to be established in an appropriate experimental format. It was chosen to use the 96 well plate format which allows to conduct the screens with a considerable low amount of plates and in an acceptable time frame. The robustness of the 96 well plate assay had to be assured since it was crucial to generate primary data of high quality to minimize the amount of false positive or false negative host cell targets. In this context, especially the reliability of the semi-automatic FACS acquisition using the FACS Calibur with HTS supply was verified intensively. To do so, an adequate human tissue culture cell line had to be found. The FACS analysis of different cell lines that had been infected with the *Salmonella* Typhimurium reporter strain revealed remarkable differences with respect to the permissiveness to the bacterial infection. Although different epithelial cell lines are exerted for *in-vivo* *Salmonella* infection experiments, an integrated comparison with respect to invasion efficiency and replication capacity has not been reported yet. Therefore, the results from the respective studies conducted in this work should be able to give recommendations for the proper cell culture model for *Salmonella* infection. Hec1b is a cancer cell line derived from an endometrial adenocarcinoma (Kuramoto *et al.*, 1972). So far, no reports have been published concerning *Salmonella* infections with the cell line Hec1b. Also for HepG2, a liver carcinoma cell line (Aden *et al.*, 1979), no reports for the permissiveness to *Salmonella* infections are available. On the other hand, the colon cancer cell line HT-29 has been used casually as a model for polarized epithelial cells in *Salmonella* infection (Raffatellu *et al.*, 2005, Mellor *et al.*, 2009) and the cervix adenocarcinoma cell line HeLa is the standard epithelial cell culture model for *Salmonella* infections. Although these cell lines are all from the epithelial lineage they differed significantly in their permissiveness to *Salmonella* infection which became obvious from the visual analysis and the respective quantification of FACS experiments (see figure III.4). The initial invasion rate (i.e. the percentage of infected cells) was comparable for all cell lines except for HepG2, although the amount of entered bacteria was dramatically different, as could be shown with the GFP fluorescence. Since HepG2 cells tend to grow in colonies, thereby building up clumps of cells, if not seeded on plastic coated with extracellular matrix components, the access to these cells might have been aggravated, explaining the lower invasion rates. Additionally, the responsiveness to *Salmonella* triggered uptake mechanisms might have been variable in the different cell lines, explaining the varying amount of bacteria that entered the cells at an early time-point. With respect to bacterial replication, the observed differences between the cell lines were even more dramatic. The number of infected cells as well as the fluorescence intensities for both GFP and mCherry was significantly lower in HT-29 cells than in any other cell line tested. As the ability of the reporter strain to grow in these cells was very weak, HT-29 cells proofed to be an unsuitable cell line for further experiments. The same was true for HepG2 cells, where only weak infection parameters could be observed. The cell lines Hec1b and HEp-2 instead showed to be very permissive to *Salmonella* infections, because the invasion and replication parameters were comparable to those of HeLa cells. Nevertheless, the dot plot analysis of the mCherry fluorescence showed that two populations of infected cells had emerged, one

showing a good response to the arabinose trigger and another one that exhibited lower mCherry fluorescence intensities. This could argue for a heterogeneous infection process in these cells, probably also for an inherent heterogeneity among the cell lines, which also made these cell lines no proper infection models for the screening experiments. Therefore, the cell line HeLa was chosen for the subsequent experimental work, as it showed to be the best cell line for infections with the reporter strain.

Suitable infection conditions in the 96 well plate format using the HeLa cell line were determined employing different multiplicities of infection (MOI), i.e. the number of bacteria per host cell. It became obvious that high numbers of bacteria, while producing very good infection rates also provoked significantly high cell toxicity, most likely by triggering apoptotic and/or necrotic pathways of the host cell. A MOI of 20 was chosen for the screening experiments since the cell toxicity was tolerable and the invasion rate was about 50 %. Due to the fact that only every second host cell was infected, it had to be assured that the siRNA transfection prior to infection yielded a very high transfection rate to rule out the possibility that a considerable amount of non-transfected cells could be infected. This might lead to unstable phenotypes during the screen and probably also to more false-negative results. Therefore, the transfection conditions were adjusted to gain a very high transfection rate, which was estimated to be nearly 100 %, using the Qiagen Biorobot 8000 and a small amount of cells (approximately 3000) in 96 well format plates (Nikolaus Machuy, personal communication). The toxic siRNA control targeting the human polo-like kinase 1 (PLK1) served as a direct transfection control and the threshold was set to < 5 % cells detected compared to Allstars treated cells. This threshold was achieved in every experimental run, demonstrating adequate and reliable transfection conditions. Interestingly, the median GFP fluorescence intensity of infected cells was independent of the MOI that was applied for infection (see figure III.7.C). This was an unexpected finding as the number of infected cells was significantly dependent on the amount of bacteria used. The equal GFP intensity might have different reasons: The initial amount of bacteria that was taken up by the cells could be identical for every MOI, which would suggest that only a limited number of cellular “invasion platforms” do exist, resulting in an equal number of entering bacteria. However, the observed differing GFP intensities at early time-points for cells infected with varying MOIs would argue against this. Another possibility is that for every *Salmonella*-infected cell a critical number of intracellular bacteria is acceptable, a phenomenon likely to be controlled by the bacteria through a quorum-sensing like process, to prevent killing of the cell. This would then lead to an equal mean GFP fluorescence of infected cells with different MOIs.

Before performing the high-throughput RNAi screening experiments, a small inhibitor screen was conducted. Several antibiotics as well as inhibitors of host cell pathways were applied and the FACS assay was used in 96 well plate format to evaluate their impact on *Salmonella* replication. For most of the antibiotics and for some of the inhibitors a decrease in GFP as well as mCherry fluorescence could be observed with rising concentrations. Another important aspect of the assay is its capability to give information on cell toxicity, reflected by the number of detected cells. Therefore, this assay is also useful in screening experiments with small compound libraries to identify new compounds with antibacterial properties. These compounds could either directly target bacterial metabolism or indirectly inhibit bacterial growth by influencing important host cell pathways. The impact on host cell survival could also be evaluated which would give a first hint on the tolerance of new compounds.

After having evaluated the proper infection conditions and the overall stability of the assay, the RNAi screening was performed. Two siRNA libraries were employed, the SOS library and

the SKV library. The SOS library consisted of ten 96 well plates and the plates were allocated “in-house” with siRNAs of different biological functions, resulting in an only moderately functionally biased library. The SKV library was a commercially available library (Qiagen, Hilden; <http://www1.qiagen.com/products/genesilencing/librarysirna/sirnasets/humanvalidatedkinase.aspx>) covering the whole human kinome. The genes targeted by this library had been derived from experimental data or from theoretical predictions based on sequence similarities to known kinases. The SKV library was declared to be knock down proven, thus, the knock down efficiency of all siRNAs of this set had been checked on mRNA levels by the company, although this was performed in different cell lines and no complete list of the results is available. Additionally, for every gene target two siRNA sequences were distributed on different plates to enable an easier pre-selection of “hits”.

Kinases are central regulators of many cellular processes, such as cell division, apoptosis, cell development, or signaling and are therefore attractive targets for pathogens to reprogram the host cell. Hence, the main focus of the screening, the data analysis, the validation, and the follow-up work was put on the kinome-wide library. The accumulated primary data from both libraries was carefully analyzed statistically to be able to decide on candidates for validation. The comparison of the results from both libraries gave interesting indications for the quality of the libraries. First, the overall toxicity of all siRNA sequences from both libraries was evaluated. For this, data for the number of detected cells from at least triplicate values was normalized to Allstars and plotted in quantitative order (see figure III.16.B). It was observed that the SOS library had a significantly higher toxicity compared to the SKV library. Here, about 60 % of all test siRNAs resulted in a considerable cell loss (i.e. cell count < 0.4 compared to Allstars). In contrast, the SKV library contained only about 30 % of toxic siRNAs. Thus, in the case of the SOS library two thirds of all siRNAs were already excluded from further analysis because of their toxicity. This probably also removed potentially interesting host cell genes and therefore the quality of the SOS library could be reviewed as inadequate, at least under the conditions applied in this setting. The higher amount of toxic siRNAs in the SOS library compared to the SKV library could be founded in the fact that the siRNAs of the SOS set were designed a couple of years before the SKV sequences and at that time the experimental knowledge of the best possible siRNA sequence design to avoid toxicity and off-target effects was less than today. Additionally, the SOS library contains a lot of apoptosis related target genes or target genes involved in transcription and translation which are likely to have a dramatic negative survival effect when depleted. Nevertheless, the SOS screening had its relevance as a proof-of-principle screen to test all experimental steps of the assay under high-throughput conditions, even though the usefulness with respect to the identification of critical host cell factors has to be assessed as marginal.

Within the primary screen of the SKV more than 70 target sequences resulted in a phenotypic shift that was regarded as significant. Due to technical limitations, only 48 of them (the strongest candidates) were selected for further validation. Interestingly, for all of these candidates only one out of the two sequences yielded the phenotype, whereas the other either showed a significant cytotoxicity or generated no phenotypic change. Such a result was not expected since the supplier of the library had claimed that all siRNA sequences were knock down validated and therefore a phenotype, if specific to the gene knock down, was anticipated for both siRNAs. The rationale behind this result could be that the observed phenotypes were not specific to the gene knock down but were rather based on unspecific effects of the respective siRNA treatments (e.g. off-target effects), and therefore, most likely, would not be strong enough to remain during the validation rounds. Furthermore, the knock down efficiency of the siRNA sequences could have had a high

variation, although validated sequences were proposed for the library. Most likely, an interplay of both matters was responsible for the outcome of the primary SKV screening data. The primary, unvalidated SKV hit list contained kinases of several different functions, making it hard to speculate whether distinct host cell pathways were enriched (see figure III.19). Interestingly, the number of targets that resulted in an upregulation of the infection exceeded the inhibitory siRNAs. If one assumes an equal statistical detection accuracy for both phenotypes (up and down), this implies that the majority of host cell kinases rather have an inhibitory function towards *Salmonella* intracellular replication than a stimulatory one. Although enriched kinase pathways were not obvious among the primary SKV data, three targets that resulted in a down-regulation of the infection could be identified that are located in one functional pathway, namely MAP3K7, MAP3K7IP1, and MAP2K7. All of them are involved in the cellular response to pro-inflammatory cytokines and environmental stresses and lead to the activation of the effector kinase c-Jun N-terminal kinase (JNK) (Wang *et al.*, 2001, Tournier *et al.*, 1999). Although JNK itself did not emerge as a primary hit, these results could point to a role of the JNK pathway during *Salmonella* infection. JNK exists in three forms, JNK1, JNK2, and the neuronal-specific JNK3 (Bode *et al.*, 2007). JNK1 and JNK2 have distinct as well as overlapping functions and therefore, it might be possible that the function of one JNK isoform was substituted by another JNK species after the respective knock down. A closer look with regard to JNK1 revealed that both sequences caused no significant change of the infection phenotype. This would argue against a role of JNK1 itself but, nevertheless, JNK1 was considered to be an interesting candidate for later follow-up studies for which other siRNA sequences should be tested.

Surprisingly, the primary SKV candidate list did not contain any of the kinases or kinase related genes that were identified within a kinome-wide screen performed by Kuijl *et al.* (2007), published during the accomplishment of this work. This was probably due to different infection models since in the publication the breast cancer cell line MCF-7 and the *Salmonella* Typhimurium strain SL1344 were used. It was described that the histidine auxotroph strain SL1344 has a cell division defect in cell culture infections (Henry *et al.*, 2005) and therefore it might not be a suitable strain for these experiments. The pro-survival serine/threonine kinase Akt1 (Song *et al.*, 2005), also known as PKB was identified by Kuijl *et al.* as a central regulator of *Salmonella* replication inside epithelial cells. It was described that Akt1 is transiently phosphorylated at an early infection time and thereby inhibits apoptosis of infected epithelial cells (Knodler *et al.*, 2005a). It has to be noted, that the primary data that was provided by Kuijl and colleagues was not very well structured. Additionally, only the data from one out of three experimental runs can be inspected, and thereby it is difficult to comprehend why Akt1 was considered an important target for *Salmonella* infection because the inhibitory effect of Akt1 knockdown was only in a moderate range as compiled from the primary data list. In addition, it was reported that the data from the siRNA screening experiments could be confirmed with shRNA constructs targeting the human kinome. However, there was hardly any phenotypic change using any of these constructs, as provided within the supplementary information. Within the screen of my work, both sequences targeting Akt1 did not lead to a relevant phenotypic alteration of the infection. Moreover, one of the sequences caused significant cytotoxicity. This seems very plausible keeping in mind that Akt1 is a crucial anti-apoptotic factor and, indeed, the activity of Akt1 is increased in many forms of cancer (Altomare *et al.*, 2005). In order to verify the candidates presented by Kuijl *et al.*, four siRNA sequences against all of the 14 published targets were purchased and tested with the FACS assay again (see table S.3). Using four different sequences for every target, there was no significant overlap between both data sets. Summing up, the

work of Kuijl et al. did not appear very convincing and thereby a comparison with the data generated within my kinome screen seemed to be very difficult.

48 candidate genes were nominated for further validation, among them 20 down-regulating targets and 28 which caused an increasing infection phenotype upon knock down. For each gene target four separate siRNA sequences were ordered and tested in 96 well plate format. During the validation 32 possible hits could not be confirmed (i.e. 75%) which was in accordance to experiences of others, showing that commonly only about 20% of primary hit candidates can be verified with solid validation experiments (Nikolaus Machuy, personal communication). The complete list of the remaining 16 targets together with their validation results can be seen in table III.2. Surprisingly, most of the factors showed an opposing phenotype in the primary screen and the validation round, which suggested that either the primary data or the data derived from the validation experiments was based on non-specific, but reproducible knock down effects. Only four of the validation targets (PGK1, MAP2K7, MKNK2, and MAP3K7) gave comparable results with more than two out of four siRNA sequences, which classified these factors as more interesting than the others. PGK1 showed the same phenotype in the primary screen and the validation during which all sequences gave comparable results. However, since PGK1 is a kinase involved in sugar breakdown it was suggested that this factor fulfils a housekeeping gene function and would therefore have an indirect influence on *Salmonella* growth. Hence, PGK1 was excluded from further analysis. MKNK2 and MAP3K7 showed opposing phenotypes in the primary screen and the validation and were therefore also not considered for follow-up experiments, leaving, at this stage, MAP2K7 as the most interesting factor. The depletion of MAP2K7 had an inhibitory impact on *Salmonella* intracellular replication in both the primary screen and the validation. Within the validation, three out of four siRNA sequences showed the same phenotype. Therefore, the role of MAP2K7 (also named MKK7) during *Salmonella* Typhimurium infection of epithelial cells was further investigated.

MKK7 belongs to the group of mitogen-activated protein kinases (MAPK) which are central regulators of diverse cellular processes like apoptosis, growth, differentiation, or inflammation. MAPKs transmit extracellular signals, e.g. from growth factors or apoptotic stimuli, in the form of a signaling cascades into the cell and shape a cellular response either by directly activating other regulatory proteins or by inducing specific transcriptional activities (Zhang *et al.*, 2007). MKK7 is mainly involved in the cellular response to pro-inflammatory cytokines and other environmental stresses. MKK7 can be activated by different upstream kinases, LZK (Ikeda *et al.*, 2001), MAP3K1 (Wu *et al.*, 1997), MAP3K4 (Abell *et al.*, 2007), DLK (Merritt *et al.*, 1999), and TAK1 (Hammaker *et al.*, 2007). Extracellular signals leading to MKK7 activation are mainly the pro-inflammatory cytokines IL-1 and TNF- $\alpha$ , transmitted via DLK and TAK1. Additionally, signals from growth factor receptors, forwarded via the Ras-Rac protein signaling pathway, are able to stimulate MKK7 (Foltz *et al.*, 1998). Once in an active state, MKK7 specifically induces JNK activity whereas the functionally related MAPK MKK4 is able to stimulate both JNK and p38, leading to a diversity of physiological outcomes that still have to be deciphered (Wang *et al.*, 2007). JNK, also named stress-activated protein kinase 1 (SAPK1) is able to activate several transcription factors. Among these are c-JUN, a component of the activator protein-1 (AP-1) complex which binds to specific promoter sites leading to transcription of several genes (Shaulian *et al.*, 2002) and ATF-2, a transcription factor binding both to AP-1 and cAMP response element promoter elements (Gupta *et al.*, 1995). In summary, JNK activation mainly leads to pro-inflammatory and apoptotic cell responses, but dependent on cell type and way of activation it is also important for cell differentiation and growth.

*Salmonella* Typhimurium activates JNK in infected cells which leads to the expression of the chemokine IL-8 (Hobbie *et al.*, 1997). It was reported that JNK together with the extracellular-regulated kinase (ERK), another member of the MAPK group, can stimulate the expression of cytosolic phospholipase A<sub>2</sub>  $\alpha$  (cPLA2) (Van Putten *et al.*, 2001). Moreover, MAPKs are able to phosphorylate cPLA2, thereby enhancing its activity (Lin *et al.*, 1993, Borsch-Haubold *et al.*, 1998, Hefner *et al.*, 2000). PLA2 catalyzes the release of arachidonic acid (AA) from host cell membrane phospholipids which serves as an important second messenger for cellular stress pathways (Chakraborti, 2003). Interestingly, it was reported that the activation of cPLA2 is necessary for *Salmonella* invasion into epithelial cells (Pace *et al.*, 1993). This indicates that the activation of the MKK7-JNK-cPLA2 pathway might be involved in bacterial invasion. For another intracellular pathogen, *Chlamydia trachomatis*, it could be shown that the activity of cPLA2 is important for intracellular growth by providing free fatty acids metabolized by the intracellular bacteria (Su *et al.*, 2004). Intriguingly, *Salmonella* Typhimurium encodes an effector protein, SseJ, which is secreted into the host cell harbouring an enzymatic activity similar to cPLA2 (Lossi *et al.*, 2008) and a *sseJ* mutant is slightly attenuated in a mouse infection model (Ohlson *et al.*, 2005), implying that the deacylase activity is important for intracellular survival, probably by modulating the SCV membrane or by delivering fatty acids to the bacteria. Therefore, the role of cPLA2 and its possible regulation via the MKK7-JNK pathway during *Salmonella* infection was investigated in more detail in this work.

The inhibitory effect of MKK7 depletion on *Salmonella* replication was studied in more detail using both siRNA and shRNA mediated silencing strategies. With both knock down methods decreased replication rates could be observed, demonstrating that MKK7 is involved in the intracellular growth of *Salmonella* (figure III.21). The relatively mild level of about 40 % inhibition was maybe due to a subordinated importance of MKK7 for *Salmonella* growth. Most likely, the pronounced redundancy among kinases, and especially members of the MAP kinase pathways, could account for this. For example, MKK4 is also able to phosphorylate JNK (Lin *et al.*, 1995); thereby it could substitute MKK7 to some extent in MKK7 depleted cells. Interestingly, the mCherry expression of bacteria in MKK7 depleted cells was in a normal range, indicating that MKK7, unlike Rab7, does not play an essential role during *Salmonella* infection but rather contributes, among other factors, to bacterial replication.

The activation of cPLA2 during *Salmonella* infection of HeLa cells was determined by measuring the phosphorylation of cPLA2 and the enzymatic activity using a specific substrate. A very early phosphorylation of cPLA2 upon infection with *Salmonella* was observed. This phosphorylation was sustained over the whole infection period, indicating that cPLA2 was constantly active (figure III.22). Interestingly, this was also the case in the chloramphenicol treated sample, although on a lower level, which suggests that the cPLA2 activity was induced in a robust way during the first two hours of infection. This could have been mediated by a secreted bacterial factor which either targets cPLA2 itself, thereby keeping it in an activate state or by inhibiting a host cell factor which de-phosphorylates cPLA2. The chloramphenicol experiment also shows that bacterial replication is probably not absolutely necessary for the cPLA2 activation, again arguing for an early event. The early and sustained activation implies that the enzymatic activity of cPLA2 is necessary for the intracellular lifestyle of *Salmonella*. This assumption was further supported by the results from gentamicin protection assays in cPLA2 depleted cells. Here, a significant reduction of intracellular replication could be observed compared to infected control cells (figure III.23). When investigating the impact of MKK7 depletion on cPLA2 phosphorylation, it was

observed that total protein levels of cPLA2 but not the relative phosphorylation levels were reduced (figure III.24). This suggests that MKK7 is not a kinase for cPLA2 but does play a role in controlling cPLA2 protein turnover. A possible underlying mechanism could have been that MKK7 directly or indirectly influenced the protein stability of cPLA2, probably through a protein complex formation after stimulation. In this case, the depletion of MKK7 would destabilize cPLA2 and therefore target it for degradation pathways. A similar process has been described for inhibitor of apoptosis protein (IAP)-complexes (Rajalingam *et al.*, 2006). Alternatively, MKK7 could control cPLA2 levels at the transcriptional level by regulating the JNK-dependent expression of the cPLA2 gene (Van Putten *et al.*, 2001). A non-specific RNAi mediated degradation of cPLA2 mRNA after transfection with MKK7 siRNA seems unlikely since the effect was observed with two distinct MKK7 sequences. Moreover, sequence alignments revealed that there are only marginal matches of the MKK7 siRNA sequences inside the cPLA2 mRNA. Nevertheless, off-target mediated cPLA2 degradation cannot be ruled out totally. In order to test whether MKK7 and cPLA2 form a complex, co-immunoprecipitation experiments were performed using antibodies against both MKK7 and cPLA2 for pull-down. When the lysates were probed for cPLA2 and MKK7, no stable complex formation could be identified after infection with *Salmonella* (see figure III.25). The fact that an interaction could not be induced with either PMA or LPS, two distinct pro-inflammatory stimuli, argues against a possible MKK7 mediated stabilization of cPLA2 upon environmental stresses. Therefore, it was tested whether MKK7 controls cPLA2 at the level of transcription. HeLa cells were treated with different siRNAs against MKK7 or cPLA2 and three days later the relative amount of cPLA2 mRNA was quantified by RT-PCR. Interestingly, the MKK7-treated samples displayed lower cPLA2 mRNA levels (figure III.26). This was the case for both MKK7 sequences and the MKK7 sequence pool, making off-target effects of the MKK7 siRNAs unlikely. This result indicates that the knock down of MKK7 down-regulates the expression of cPLA2 (likely due to weaker JNK signaling activity), implying that the inhibitory impact of MKK7 depletion on *Salmonella* growth is rather an indirect than a direct one: The knock down of MKK7 negatively regulates the basal cPLA2 protein levels in the cells which negatively influences the bacterial intracellular growth.

The functional role of cPLA2 for *Salmonella* intracellular growth was ascertained further by comparing the structure and appearance of *Salmonella*-induced filaments (Sifs) in Allstars and cPLA2 siRNA treated cells. Sifs are formed along microtubules and are enriched in the lysosomal marker protein LAMP-1 (Garcia-del Portillo *et al.*, 1993, Brumell *et al.*, 2002). It has been reported that the formation of Sifs at early time-points of infection is a highly dynamic process with Sifs branching, extending, or contracting. At later time-points of infection Sifs seem to stabilize and form a regular network displaying a less dynamic behaviour which certainly indicates a form of final maturation step (Rajashekar *et al.*, 2008, Drecktrah *et al.*, 2008). Therefore, the structure of Sifs might give an indication about the successful accommodation of *Salmonella* inside its host cell. Interestingly, a large proportion of cPLA2 depleted cells infected with *Salmonella* Typhimurium showed needle-like, filiform Sif structures which could be immature, non-stable Sif elongations. These structures were only marginally seen in Allstars-treated cells. Here, robust Sifs with a thicker appearance dominated (figure III.27). This observation suggests that cPLA2 is involved in the correct maturation of Sifs. As mentioned earlier, *Salmonella* encodes an effector protein (SseJ) with similar function to cPLA2, and maybe these two proteins complement one another in their enzymatic properties to allow different lipid modifications of the Sif membrane which are crucial for the structural maturation of Sifs. Although it was not successful to immunostain

cPLA2 using two different antibodies, it could be possible that cPLA2 is recruited to the SCV membrane and to Sifs.

In summary, in this work it could be established that MKK7 controls cPLA2 at the transcriptional level and that cPLA2 is involved in *Salmonella* intracellular growth. This is likely mediated by its enzymatic activity towards membrane phospholipids which contributes to the correct formation of mature Sifs, a prerequisite of successful *Salmonella* replication.

## Outlook

Within a kinome RNAi screen, the MAPK MKK7 was identified as an important factor in the replication of *Salmonella* Typhimurium inside human epithelial cells. The depletion of MKK7 from cells led not only to a reduction of bacterial replication but, moreover, to a significant decrease in cPLA2 mRNA levels and thereby to reduced protein levels. This pointed to a role of cPLA2 during *Salmonella* infection which, indeed, could be demonstrated with cPLA2 depleted cells. The precise role of cPLA2 during *Salmonella* infection could not be clarified but initial observations made during this work point to a role of cPLA2 in Sif formation. Hence, a cPLA2 mediated modification of the SCV and Sifs could be important for the integrity of the membrane or the elongation of Sifs and should be further investigated. In this context, the localisation cPLA2 in *Salmonella* infected HeLa cells would be of great interest and therefore ectopically expressed fluorescence-tagged cPLA2 would be useful. Additional studies with *Salmonella* mutant strains which are depleted of SseJ, an effector protein that possesses functions similar to that of cPLA2, might give further important insights into the process of Sif formation during *Salmonella* infection.

Also, the signaling pathways leading to a downregulation of cPLA2 expression upon MKK7 knock down have to be analyzed in more detail. It seems likely that cellular homeostasis pathways are altered upon MKK7 depletion. For example, the response to growth factors mediated by the Rac1-MEKK4/12-MKK7-JNK pathway could be affected. To evaluate this, specific knock down experiments should be helpful.

Since the bichromatic FACS assay proved to be a powerful tool for quantifying intracellular replication and metabolic fitness of *Salmonella* Typhimurium in different human cell lines, it is valuable for further investigations of cellular factors, such as small GTPases. Many of them (Rab proteins) are involved in endosomal trafficking processes which have been described to be important for *Salmonella* infection (Kuhle *et al.*, 2006, Drecktrah *et al.*, 2007). In order to gain a complete picture of essential host cell factors for *Salmonella* infection, a screening approach using a human whole genome siRNA library would be the best strategy. However, this brings about new experimental challenges. The large amount of siRNAs makes it necessary to work with a 384 well plate format which premises totally automated working processes. Additionally, the amount of data acquired during genome-wide screens dramatically exceeds the data sets of limited RNAi libraries. Therefore, a reliable way of automated analysis would have to be installed. Thus, whole-genome wide screens have to be established very robustly as there is nearly no possibility to manually evaluate the primary screening results.

It would also be very interesting to compare different intracellular pathogens with regard to the specific infection pathways that have evolved. In principal, a similar FACS assay should be feasible for other bacteria suppositional that plasmid-based reporter systems are accepted in respective pathogens.

---

Apart from the employment for RNAi screens, the assay established in this work can also be used for high-throughput compound screens to identify new antibacterial drugs. This has been performed on a small scale but should also be practicable on a larger dimension.

## VI Acknowledgement

Prof. Dr. Thomas Meyer for the great opportunity to perform the experimental work for my doctoral thesis in an excellently equipped laboratory within a very good scientific environment and his permanent and supportive interest in my project

Dr. Nikolaus Machuy for helping me with all RNA interference issues and for structural suggestions during the assay development

Dr. Dagmar Heuer for good scientific discussions and some ideas for follow-up experiments; unfortunately time was limited

Current and former members of the lab 2.47 and the office 2.38, especially Bianca, Manuel, Malvika, Jura, Manuela, Andi and Munir for endless chats (about science and life) and a lot of fun

Jörg and Anja for technical assistance

All other colleagues of the department

Björn and Kalle for Mini Bar, West Germany, Cake, Privatclub evenings; always a good way of recreation

My parents, who most likely don't have a clue of what I was doing the last years inside this building but certainly have their share in paving the way

Most of all, I want to express my greatest thankfulness to Linda. Her love, faith, patience, (comma!) and scientific expertise are of inestimable value for everything that was and everything still to come. You are the lady in my life!

## **VII SUPPLEMENTARY INFORMATION**

### **VII.1 Curriculum vitae**

## VII.2 Publications

**Riede, O.**, Heuer, D., Machuy, N., Meyer, T.F. „Kinome-wide RNAi screen identifies MKK7 dependent regulation of *Salmonella* replication by controlling cPLA2 levels” (in preparation)

## VII.3 Talks and posters

- 2009**    **1st Joint Congress of the Swiss and German Societies of Cell Biology, Konstanz.**  
 „Global analysis of host cell functions affecting *Salmonella* intracellular growth.”  
 (Poster)
- 2008**    **Symposium „Fachgruppe Mikrobielle Pathogenität“, Bad Urach.**  
 „Global analysis of host cell factors essential for intracellular growth of *Salmonella* Typhimurium.” (Oral presentation)
- 2007**    **Fourth Annual EIMID Meeting, Norton Park, UK.**  
 „Bichromatic flow cytometry high-throughput assay for quantifying bacterial intracellular survival.” (Poster)

## VII.4 Supplementary data

**Figure S.1: 96 well plate scheme**

**Figure S.1: 96 well plate scheme for automatic transfections.**

The scheme shows the general allocation of 96 well plates for the automatic siRNA transfections. The outer wells (white) were left untreated due to observed unusual cell growth behaviour but filled with medium as well. The controls were pipetted into the outer columns (B2-G2 and B11-G11) of the 60 analysis wells and the siRNAs to test were transferred into the 48 wells coloured in grey (B3-G10) according to the order they were allocated in the transfection plates. Controls were: Allstars (yellow), PLK1 (blue) and Rab7A\_2 (red).

**Table S.1: Complete list of kinase library screening results in quantitative order**

**Figure S.4: Principle of multi-parametric flow cytometry****Figure S.4: Principle of multi-parametric flow cytometry.**

The schematic illustration shows the principle of multi-parametric flow cytometry as implemented in the FACS Calibur. Particles delivered by the fluidics subsequently pass two laser beams and their characteristic light scattering and light emitting properties can be monitored and amplified by different detectors. The data for every parameter can be saved and analyzed on a single cell level.
